Executive Summary

The South Dakota Department of Environment and Natural Resources (department) develops an annual ambient air monitoring network plan which is a review of the ambient air monitoring network each year as required by Title 40 of the Code of Federal Regulation (CFR), Part 58. The review finds the state's ambient air quality concentrations are demonstrating attainment with EPA's National Ambient Air Quality Standards (NAAQS).

The annual plan is published in the department's air quality website to provide public review and comments so adjustments can be made to meet the needs of the general public before the annual plan is finalized. The annual plan includes the following major sections:

1. Ambient air monitoring goals, plans and needs are in Sections 3.0 through 5.0, respectively;
2. Evaluation of collected data compared to the NAAQS is in Section 6.0;
3. Determination of air pollution trends are in Sections 7.0 and 8.0; and
4. Proposed modifications to the ambient air monitoring network to meet the changing trends, national requirements, and state needs are in Section 9.0.

The department will continue to evaluate the following areas for the need to modify the ambient air monitoring network:

1. With the change in deicing operations in Rapid City, the department will continue to evaluate the need for other air monitoring sites in the city if problems with dust indicate a need; and
2. As monitoring rules are finalized by EPA there may be a need for modifications to the PM_{2.5} and ozone testing site locations.

The department is planning the following site modifications in 2012 and 2013 based on the state's needs:

1. The department will complete the replacement of the RAAS PM_{2.5} manual method monitors with Partisol 2000 PM_{2.5} manual method monitors. The RAAS PM_{2.5} manual method monitors have been discontinued by the manufacturer and replacement parts are no longer be available. Rapid City Library Site is the last site to operate the RAAS PM_{2.5} monitors and they will be replaced by the middle of 2012;
2. The department will continue to evaluate locations where continuous PM monitors can replace manual monitors in the network; and
3. The department will evaluate the need to close UC #3 and move the ozone analyzer to UC #2 or UC #1. The shelter at UC #3 is in poor condition which has allowed water and mice into the building destroying the insulation and making the building a health threat.

1.0 INTRODUCTION

The United States Environmental Protection Agency (EPA) through Title 40 of the Code of Federal Regulation (CFR) and the Performance Partnership Agreement requires the South Dakota Department of Environment and Natural Resources (department) to complete an annual ambient air monitoring network plan. EPA's requirements for the annual plan are listed in 40 CFR § 58.10. The annual plan will cover a review of the ambient air monitoring sites and determine if the network is meeting the monitoring objectives in 40 CFR Part 58, Appendixes A, C, D, and E. The annual plan will identify needed modifications to the network such as the termination or relocation of a monitor, termination of an existing station, addition of new parameters, or the establishment of new stations.

The department is required to public notice the annual ambient air monitoring network plan for 30 days prior to submitting the plan to EPA. The department will comply with this requirement by posting this document on the department's Air Quality Program website at the following location for 30 days:

<http://denr.sd.gov/des/aq/airprogr.aspx>

All comments received by the department during this 30 day period will be addressed by the department and the appropriate changes will be incorporated in the plan. If a substantial change is made to the plan because of a comment, another 30 day public comment period will be completed. The final annual plan will be submitted to EPA for review including all public comments and the department's responses to the comments.

2.0 AMBIENT AIR MONITORING NETWORK HISTORY

In 1972, South Dakota developed and EPA approved a State Implementation Plan (SIP) which included the establishment and operation of an ambient air monitoring network for the state. In 1980, South Dakota submitted a revision to its SIP to upgrade the program by establishing a network of state and local air monitoring stations (SLAMS) and special purpose monitoring (SPM) stations.

In 1985, the state set up the first samplers to test for levels of particulate matter 10 microns in diameter or less (PM_{10}) in anticipation of EPA adopting a PM_{10} National Ambient Air Quality Standards (NAAQS). In 1987, the total suspended particulate (TSP) standard was replaced with the new PM_{10} standard. South Dakota submitted a revised ambient air monitoring network plan to include sampling sites for the new PM_{10} standard and shutdown the TSP monitoring network in 1987.

A new standard was added by EPA for particulate matter 2.5 microns in diameter or less ($PM_{2.5}$) in 1997. South Dakota submitted a revised ambient air monitoring network plan to include sampling sites for the new $PM_{2.5}$ standard. In 1999, $PM_{2.5}$ samplers were added to the ambient air monitoring network to determine compliance with the new standard.

In 1997, a new standard was also set for ozone that lowered the concentration level and moved from a one hour to an eight hour average standard. Due to the standard change and concern with

the modeling results by the Ozone Transport Assessment Group, the state started an ozone monitoring network which by 2006 included sites in Sioux Falls, Rapid City, and Wind Cave National Park. South Dakota submitted an attainment designation to EPA on April 15, 2003, designating each county as attaining the new ozone standard. On April 30, 2004, EPA published a federal register notice designating each county in the state as attainment/unclassifiable.

In 2006, EPA revised the PM_{2.5} standard significantly by reducing the 24-hour standard from 65 to 35 micrograms per cubic meter. South Dakota submitted an attainment designation to EPA on December 11, 2007, designating each county as attaining the new PM_{2.5} standard. On December 22, 2008, EPA notified the department they were designating each county in the state as attainment/unclassifiable.

In 2008, EPA revised the ozone standard and reduced the standard from 0.08 to 0.075 parts per million. South Dakota is attaining the new standard and submitted a proposed attainment designation package for all counties in the state to EPA on March 6, 2009. The new presidential administration in 2009 asked EPA to stay the implementation of the new ozone standard and re-evaluate the standard. EPA decided to implement the 2008 standard in 2012 so the current standard is 0.075 ppm. The department is waiting on EPA's decision on the state's recommended designations.

The nitrogen dioxide (NO₂) standard was reviewed and a new one-hour standard was set by EPA in 2009. The annual standard was retained without any change in concentration level. The department began monitoring for nitrogen dioxide in 2003 and currently operates nitrogen dioxide monitors in Sioux Falls, Union County, Badlands, and Rapid City. South Dakota submitted an attainment designation to EPA on January 24, 2011, designating each county as attaining the new one-hour nitrogen dioxide standard. On January 20, 2012, EPA notified the department they were designating each county in the state as attainment/unclassifiable.

EPA also made changes to the air monitoring requirements for lead in 2009. The final rule did not require lead monitoring at the National Core site and all sources in South Dakota have emission levels less than 0.5 ton per year. Therefore, testing for lead is not required at this time. Based on previous lead monitoring and the types of sources in South Dakota, the department submitted an attainment designation to EPA on October 15, 2009, designated each county as attaining the new lead standard. On November 8, 2011, EPA notified the department they were designating each county in the state as attainment/unclassifiable.

The sulfur dioxide (SO₂) standard was reviewed and the 24-hour and annual standards were replaced by a new 1-hour standard set by EPA in 2010. The department began monitoring for sulfur dioxide in 2002 and currently operates sulfur dioxide monitors in Sioux Falls, Union County, Badlands, and Rapid City. South Dakota submitted an attainment designation to EPA on June 2, 2011, designating each county as attaining the new one-hour sulfur dioxide standard. The department is waiting on EPA's decision on the state's recommended designations.

Data collected from the ambient air monitoring network is entered into the federal database called the Air Quality System (AQS). Individuals interested in reviewing the air quality data can go to the EPA website at the following address: <http://www.epa.gov/airexplorer/index.htm>

3.0 AIR MONITORING GOALS

The department's Air Quality Program was established with the primary goal of protecting the health, welfare and property of South Dakotans from the detrimental effects of air pollution. The Clean Air Act of 1970 and subsequent amendments define air quality standards for various air pollutants necessary to protect the public from injurious pollution concentrations. Air pollution concentrations that exceed these established standards can cause "a public health hazard, nuisance, annoyance or damage buildings, property, animals, plants, forests, crops, exposed metals or otherwise interfere with the enjoyment of life or property."

In order to attain and maintain the NAAQS, the department developed regulations that restrict air pollution from sources, establishes these restrictions in an air quality permit, requires periodic inspections to ensure compliance, and maintains an ambient air monitoring network to provide air quality information and monitor the success of the Air Quality Program.

4.0 AIR MONITORING PLAN

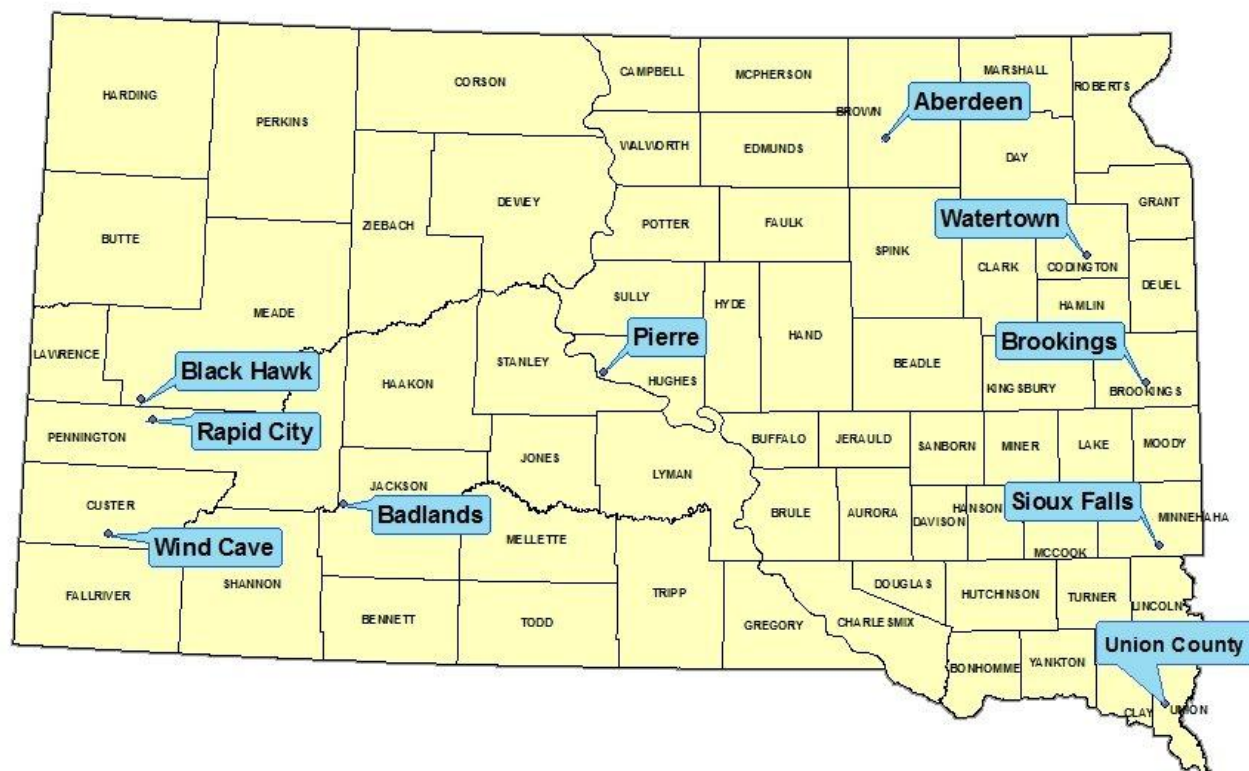

In calendar year 2011, the ambient air monitoring network included 16 ambient air monitoring sites. Figure 4-1 shows a map of the general locations and cities with ambient air monitoring sites at the beginning of 2011. The following types of ambient air monitors and monitoring sites are operated in South Dakota:

1. State and local air monitoring stations (SLAMS);
2. Special purpose monitors (SPM);
3. Air toxic monitors;
4. Prevention of Significant Deterioration (PSD) monitors;
5. Interagency Monitoring of Protected Visual Environments (IMPROVE) sites;
6. Environmental radiation ambient monitoring systems; and
7. National Core (NCore) multi pollutant sites.

Ambient air monitoring site files are maintained in the department's Pierre office for the SLAMS and SPM sites. The ambient air monitoring site files are available for public review during normal working hours from 8:00 AM to 5:00 PM each workday. The monitoring site files contain at a minimum the following information for each site:

1. AQS site identification form;
2. Sampling location;
3. Sampling and analysis method;
4. Operating schedule;
5. Monitoring objective and spatial scale;
6. Beginning date of operation; and
7. Site maps.

Figure 4-1 –South Dakota Air Monitoring Sites

4.1 State and Local Air Monitoring Stations (SLAMS)

A State and Local Air Monitoring Station consists of an air monitor selected by the state or local air programs to determine compliance with the NAAQS. At the beginning of 2011, fourteen of the networks sites have at least one SLAMS monitor for at least one air pollutant parameter. The sites in the network collected PM₁₀ data at twelve sites, PM_{2.5} data at eleven sites, sulfur dioxide and nitrogen dioxide at five sites, and ozone at six sites throughout South Dakota.

4.2 Special Purpose Monitoring (SPM)

A SPM monitor is a generic term for all monitors used for special studies. The data is reported to EPA, the equipment is EPA or non-EPA designated monitoring methods, and the monitoring data is used for special circumstances or needs. Five of the ambient air monitoring network sites operated some kind of SPM monitor in 2011. The parameters tested by the SPM monitors in South Dakota include:

1. Weather stations at the Black Hawk, SD School, and UC #1 sites;
2. Air toxic monitors at the SD School and UC #1 sites;
3. PM_{coarse} monitor, NO_y analyzer, and PM_{2.5} speciation monitors at the SD School Site;
4. RC National Guard Site has a SPM monitor to help define the extent of the PM₁₀ high concentration area in western Rapid City; and
5. Radiation monitors operated at the Pierre and RC National Guard sites.

4.3 Air Toxics Monitoring Sites

As part of a national research project, air monitors testing for pollutants classified as air toxics are being operated at the SD School Site in Sioux Falls and at the UC #1 Site in Union County.

Testing for air toxic parameters began in Sioux Falls at the Hilltop Site in 2000 and continued at the SD School Site in 2008. The SD School Site is located near the South Dakota School for the Deaf and the Terry Redlin Elementary grade school. The goal is to determine current concentration levels in South Dakota's largest city.

In 2002, a second air toxics site was established in Custer. This location was established because EPA's modeling estimates of air toxic emissions showed that Custer County had the potential for some parameters to be the highest ambient concentrations in the state. The city of Custer is the largest city in Custer County. In March 2008, five years of sampling data was completed at this site and concentration levels did not indicate trends that would require continuation of the site.

The Custer Site was closed in December 2008 and the equipment was moved to the UC #1 Site. The UC #1 Site is operated as part of three sites in Union County to determine background concentrations in anticipation of construction of the proposed oil refinery at the Hyperion Energy Center. At the end of 2011, air toxic sampling completed three years of testing at the UC #1 Site. No further testing is planned until the Hyperion Energy Center begins to operate so the sampling device was removed from the site.

The air toxic data is reported to the AQS database by the EPA contractor so it can be compared with other national sites and provide baseline levels for South Dakota and used in health studies. Currently, the data collected between 2000 and 2010 have been added by the EPA contractor into the AQS and the National Air Toxic Assessment database. If an individual is interested in reviewing the data they may register with EPA at:

<http://www.epa.gov/ttn/atw/natamain/>

4.4 Prevention of Significant Deterioration (PSD) Monitoring Sites

In 2011, no Prevention of Significant Deterioration monitoring project were started or completed.

4.5 IMPROVE Network

Two Interagency Monitoring of Protected Visual Environments (IMPROVE) sites are being operated by the National Parks Service in South Dakota. The site locations are at the Badlands and Wind Cave National Park. Data results for parameters collected by the National Park Service can be requested from the individual national parks at:

<http://vista.cira.colostate.edu/views/Web/Data/DataWizard.aspx>.

4.6 Radiation Network (RadNet)

The RadNet sites in Pierre and Rapid City are being operated as a part of the national network of sampling sites. The Pierre Site has been operated since the early 1980s. The state has a limited role in operating the monitor. The state collects the samples, takes preliminary readings of radioactivity levels, and ships the samples to the EPA office of Radiation and Indoor Air. The type of sample collected is airborne particulates and measurements taken are gross beta radiation levels.

In 2009, EPA requested a second site in the state to be located in the Rapid City area. The new RadNet monitor was installed at the RC National Guard Site on May 7, 2009. The site is operated by the department's Rapid City Regional Office in conjunction with the Rapid City National Guard.

The general objectives of the sampling sites are to provide a means of estimating ambient levels of radioactive pollutants in our environment, to follow trends in environmental radioactivity levels, and to assess the impact of fallout and other intrusions of radioactive materials. Specifically, the RadNet monitor was designed to:

1. Provide a direct assessment of the population's intake of radioactive pollutants due to fallout;
2. Provide data for developing a set of dose computational models for specific sources and a national dose computational model to aggregate all sources and determine total population dose;
3. Monitor pathways for significant population exposure from routine, accidental, and terrorist releases of radioactivity from major sources;
4. Provide data for indicating additional sampling needs or other actions required to ensure public health and environmental quality in the event of a major release of radioactivity to the environment; and
5. Serve as a reference for data comparison with other localized and limited monitoring programs.

The radiation data collected at this site may be reviewed at:

http://oaspub.epa.gov/enviro/erams_query.simple_query

4.7 National Core Multi-Pollutant Site

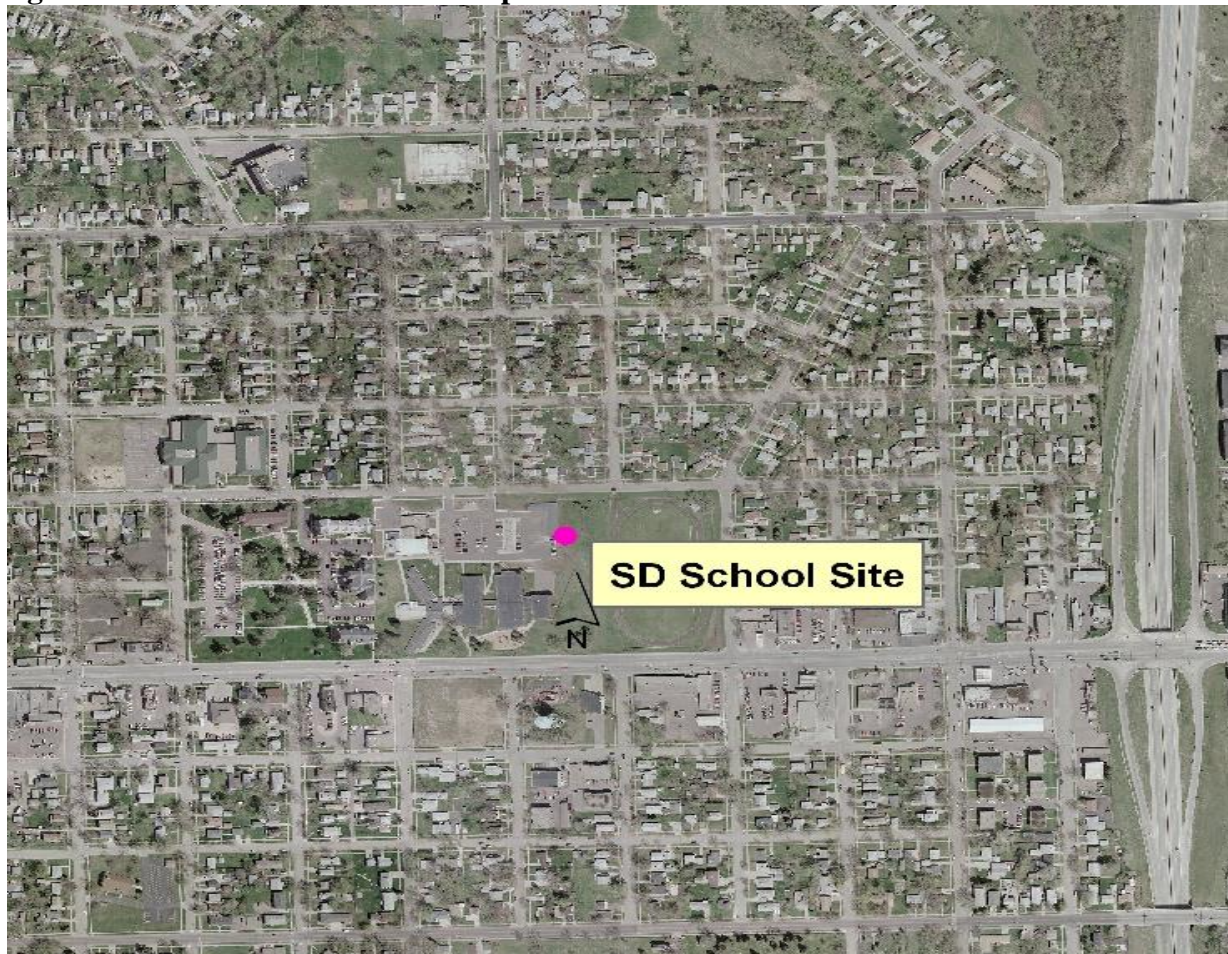

The National Core (NCore) multi-pollutant monitoring site will provide data on several pollutants at lower detection levels and replaces the National Air Monitoring Station (NAMS) sites that have existed for several years. Each state's ambient air monitoring network is required to have at least one NCore site. At the beginning of 2011, all required parameters were operating at the SD School Site. The NCore site addresses the following monitoring objectives:

1. Timely reporting of data to the public through AirNow for air quality forecasting and other public reporting mechanisms;

2. Support development of emission strategies through air quality model evaluation and other observational methods;
3. Accountability of emission strategy progress through tracking long-term trends of criteria and non-criteria pollutants and their precursors;
4. Support long-term health assessments that contribute to ongoing reviews of the NAAQS;
5. Compliance through establishing nonattainment/attainment areas by comparison with the NAAQS; and
6. Support multiple disciplines of scientific research including public health, atmospheric and ecological.

The NCore site in South Dakota is located on the School for the Deaf campus in Sioux Falls, which is identified as the SD School Site (46-099-0008). This site meets the location requirements to be in an urban residential area. Sioux Falls was selected as the NCore site for South Dakota because it is the largest city in the state and is one of the state's fastest growing communities. See Figure 4-2 for an aerial view of the city around the SD School Site.

Figure 4-2 – SD School Site Area Map

The NCore site collects data for trace level sulfur dioxide (SO₂), nitrogen oxides (NO_x), all reactive oxides of nitrogen (NO_y), carbon monoxide (CO), ozone (O₃), PM_{2.5} continuous and

filter based manual monitors, PM_{10-2.5} mass, PM_{2.5} speciated, PM₁₀, and meteorological parameters of wind speed, wind direction, relative humidity, and ambient temperature.

5.0 AMBIENT AIR MONITORING NEEDS

5.1 Monitoring State's Largest Population Centers

South Dakota's industrial base and population centers are typical of the northern plains states. The largest industry in the state is agriculture. Most of the other industries are located in several localized areas. The industries in these locations are typically small (less than 50 employees) and generally do not produce large quantities of air pollutants. Most are considered service oriented businesses or light industrial. The only heavy industrial facilities are the Big Stone Power Plant in Grant County and the quarry area in Rapid City.

The population distribution of the state follows the general industrial distribution. Most of the state's population of 814,180, in the 2010 Census, lives either on the eastern or western third of South Dakota. The two largest cities in South Dakota are Sioux Falls and Rapid City located in southeastern and western South Dakota, respectively. The remaining population is primarily spread across the eastern third of the state with the remaining portion of the state sparsely populated. See Table 5-1 for a list of the ten largest cities and Table 5-2 for a list of the 10 largest counties in the state.

Table 5-1 – 10 Largest Cities in South Dakota

Ranking	City Name	Counties	Population

Given South Dakota's population distribution, most of the air monitoring efforts of the state have in the past been concentrated in the areas of high population. Within these areas of high population, monitoring sites are chosen that will determine areas of high pollution concentration, determine if the NAAQS are being met, identify and attempt to quantify pollutant concentrations emitted by industries, and identify sources that have the potential to release large amounts of pollutants. Air monitoring sites are currently being operated in or near the five largest cities and seven largest counties in the state.

5.2 Real Time Data

Air monitoring goals have shifted to the collection of data using continuous air monitoring samplers and providing the data as quickly as possible for the public to use. Continuous samplers provide more data at lower operational cost, which is necessary as EPA continues to expand ambient air monitoring programs for the same amount of funding or less. In many cases the continuous emission monitoring can be accessed by telephone and uploaded to a website for public use. The public can then use this data to determine if they need to take extra precautions when doing outdoor activities. The real time information is used to monitor PM₁₀ and PM_{2.5} concentrations when high wind dust alerts are forecasted for Rapid City and is provided to the public on South Dakota's website at:

<http://denr.sd.gov/des/aq/aarealtime.aspx>

In 2011, data uploaded from the PM_{2.5} monitor and ozone analyzer at Wind Cave, Badlands, and SD School sites were reporting hourly data to EPA's AirNow website at:

<http://www.airnow.gov/>

This data along with other monitoring sites around the nation provides the public and EPA with near real time data to show current air pollution levels and forecast levels for long range transport. The goal for the future is to add other locations in the state to this website and to the department's website.

5.3 Class I Areas

With the development of coal bed methane production in Wyoming and Montana and the potential for new coal fired power plants in and out of the state, there is a growing need for data in rural and small cities. In addition, South Dakota must develop a plan to implement the regional haze regulations required by the federal Clean Air Act. The implementation of these regulations will put more importance on air pollution levels in the state's two class I areas of Badlands and Wind Cave National Parks.

Ambient air monitors were placed in these areas in order to determine background levels and the impact of long range transport of air pollutants like particulate matter, ozone, sulfur dioxide, and nitrogen dioxide. In addition, continuous data is needed for modeling purposes to help in determining air quality permit requirements. The National Park sites collect data from IMPROVE monitors for PM₁₀, PM_{2.5}, and chemical analysis of the collected particulates. The department collects PM₁₀, PM_{2.5}, sulfur dioxide, nitrogen dioxide, and ozone data at the Badlands Site and PM₁₀, PM_{2.5}, and ozone data at the Wind Cave Site.

5.4 Ozone Monitoring

Ozone levels in the nation are being impacted by long range transport from within the nation and internationally. In some cases, states are observing rural ozone levels higher than ozone levels in large cities. This is a serious problem for states in the eastern half of the nation in meeting the current ozone standard and beginning to be a problem in the western half of the nation. Colorado, Wyoming and Utah are having issues with high ozone levels in their rural areas with some of the highest levels coming in winter months. It will be important to maintain ozone monitoring in all areas of South Dakota to determine if long range transport of air pollution affects ozone concentration in rural and urban areas.

Past national modeling efforts show there is potential for having ozone concentrations near the standard in the east and southeastern parts of the state. Monitoring sites were added in 2008 in Union and Brookings counties to more accurately determine if the population is being exposed to high ozone levels. The eastern third of the state now has three ozone monitoring sites.

5.5 PM_{2.5} Monitoring

In 2006, EPA significantly lowered the 24-hour PM_{2.5} standard from 65 micrograms per cubic meter (ug/m³) to 35 ug/m³. EPA has currently completed a 5-year review of the PM_{2.5} standard and has proposed a change to the standard which will be published in July 2012. The proposal recommends set a lower annual standard and a secondary standard for visibility in urban areas so sampling for PM_{2.5} levels will continue to be a priority in the state.

5.6 Metropolitan Statistical Areas

40 CFR Part 58, Appendix D, contains information used to design an ambient air monitoring network and lists three basic objectives in designing an ambient air monitoring network. The three basic objects are listed below:

1. Provide air pollution data to the general public in a timely manner. The department accomplishes this objective by providing Near Real Time data on the department's website at:

<http://denr.sd.gov/des/aq/aarealtime.aspx>

The data on this website includes hourly data from the Sioux Falls and Rapid City sites. It also includes other cities like Black Hawk and Watertown sites and rural areas like

Union County, Badlands and Wind Cave sites. Specifically in the Rapid City area, High Wind Dust Alerts are called when meteorological conditions are forecasted that could cause high PM₁₀ concentrations. This information along with a report graphing hourly concentrations recorded during the alert is also provided to the public through the department's website;

2. Support compliance with ambient air quality standards and emissions strategy development. The department accomplishes this objective by locating the sites throughout the state to assess the permit control measures and pollution emission impacts on the state. For example, the Rapid City air monitoring sites specifically evaluate the permit control measures and the special measures taken to reduce fugitive dust levels; and
3. Support for air pollution research studies. The department supports research by loading the air quality data into EPA's AQS database site and by supporting local studies when requested by the state's colleges.

EPA identified in Appendix D the air monitoring requirements for ozone, carbon monoxide, nitrogen dioxide, sulfur dioxide, particulate matter, and lead. The number of required air monitoring sites for ozone and particulate matter is based on the state's Metropolitan Statistical Areas (e.g., determined by the population of the MSA and each pollutant's design value in the MSA). Each design value is specific to the pollutant and form of the standard. To determine the number of monitoring sites, the design value is calculated based on the pollutant concentration and the applicable form of the standard in 40 CFR Part 50, divided by the applicable pollutant's standard in 40 CFR Part 50, and the results multiplied by 100. The percentage is compared to the values in Appendix D to determine the minimum number of monitoring sites.

If there is no ambient air monitoring data for the MSA, only the minimum number of sites listed in Appendix D is required to be operated. If there is a minimum of three years of air quality data for the MSA, a design value is calculated. If the MSA has a design value greater than 85% of the standards for ozone and PM_{2.5} and 80% of the standard for PM₁₀ the required number of sampling sites continues to increase as the population increases. If the highest concentration site in a MSA has a design value less than 80% for PM₁₀ and 85% of the standard for other pollution parameters the required number of sites may be one or even zero depending on the design value and population of the MSA.

There is one additional ambient air monitoring requirement in Appendix D for an ozone network. If a MSA is required to have one or more ozone monitor, at least one of the ozone monitoring sites is required to be located at the expected high concentration area for the MSA.

Table 5-3 shows the population, design values and the minimum site requirements for the Sioux Falls, Rapid City, and Sioux City MSAs in the state using data through the 2011 sampling year.

Table 5-3 – 40 CFR Part 58, Appendix D Requirements for MSA

2010 MSA Population	Counties	Site	AQS ID	Maximum Design Values	> NAAQS Criteria (Yes or No)	Minimum Sites Required
Sioux Falls MSA						
169,468 44,828 5,618 8,347 Total: 228,261	Minnehaha Lincoln McCook Turner	SD School	46-099-0008	PM _{2.5} 24-hour = 68%	No	0

Union (SD),	14,399 6,000 21,006	UC #1	46-129-0001	PM ₁₀ 24-hr = 47%	No	0
Dixon- Dakota (NE), and		UC #2	46-129-0002	PM ₁₀ 24-hr = 43%		
Woodbury (IA)	102,172	UC #1	46-129-0001	PM _{2.5} 24-hr = 69%	No	0

2010 MSA Population	Counties	Site	AQS ID	Maximum Design Values	> NAAQS Criteria (Yes or No)	Minimum Sites Required
Total	143,577	UC #2	46-129-0002	PM _{2.5} 24-hr = 71%		
		UC #1	46-129-0001	PM _{2.5} Annual = 59%	No	0
		UC #2	46-129-0002	PM _{2.5} Annual = 59%		
		UC #3	46-129-0003	Ozone 8-hr = 81%	No	0

The department operates the following additional types of monitors to meet the specific network requirements in 40 CFR Part 58, Appendix D:

1. PM_{2.5} speciation monitor in Sioux Falls at the SD School Site; the largest urban area in the state;
2. PM_{2.5} background and transport monitors at the Badlands and Wind Cave sites; and
3. NCore site located in the city of Sioux Falls at the SD School Site.

Another requirement in Appendix D is providing for a Photochemical Assessment Monitoring Stations (PAMS) which is required in areas classified as serious, severe, or extreme nonattainment for ozone. South Dakota is not required to have a PAMS site.

There is no Appendix D required population air monitoring sites for carbon monoxide. The only required carbon monoxide air monitoring site is at the National Core Site. Carbon monoxide air monitoring started at the SD School Site in 2011.

There are population monitoring requirements for nitrogen dioxide but the core based statistical area (CBSA) must have a population level of 500,000 or greater. There are no population based monitoring sites required by EPA for South Dakota.

Sulfur dioxide has a population based monitoring requirement for a CBSA. The monitoring requirement is based on a calculation using the total amount of sulfur dioxide, in tons, emitted within the counties in the CBSA area and the population within the CBSA counties. The calculation is called the population weighted emissions index for the CBSA. Union County is part of the Sioux City CBSA and is the only area in South Dakota with a population weighted emissions index that has a value high enough to require a monitoring site. The EPA rules require the monitoring site to be located in the parent CBSA or Sioux City area in this case. No population weighted emissions index required sulfur dioxide monitoring sites are required in South Dakota.

The minimum requirements for lead are based on the lead air emissions from a source or airport with an annual emissions rate of 0.5 tons per year. In this case, there are no required monitoring sites in South Dakota.

5.7 Future Monitoring

There is currently minimal monitoring being completed in other parts of the state that have small, but expanding populations and industries. These areas include the northeastern and the northern Black Hills portions of the state. These areas will continue to be evaluated to determine whether additional monitoring efforts need to be conducted in those areas.

PM₁₀, PM_{2.5}, sulfur dioxide, nitrogen dioxide, and ozone will be the focus of the ambient air monitoring network as levels of these pollutants have the greatest potential to have concentrations close to the standard as EPA continues to lower the NAAQS for these pollutants.

6.0 COMPLIANCE WITH NAAQS

This section provides a comparison of the collected data to the NAAQS. The comparison will determine if an area is attaining the standard. In addition, the comparison will assist in determining if more monitoring stations for certain parameters is needed in an area or an area no longer needs to monitor for a certain parameter or parameters.

6.1 Particulate Matter (PM₁₀)

The PM₁₀ NAAQS is based on a 24-hour average concentration. The maximum 24-hour average concentration allowed is 150 micrograms per cubic meter (ug/m³). Attainment with the 24-hour standard is demonstrated when there is less than or equal to one expected exceedance per year averaged over three years. A 24-hour average concentration of 154.4 ug/m³ is the highest level that still attains the 24-hour standard for PM₁₀.

In 2011, the statewide PM₁₀ monitoring network included 12 monitoring locations. Five of the sites recorded data using manual monitors providing 24-hour sample concentrations. Seven of the sites have continuous samplers providing 1-hour concentrations. The main distribution of the PM₁₀ air monitoring sites is located in Rapid City with three sites. Two sites are operated in central Union County for preconstruction, construction and post construction of the Hyperion Energy Center. Other locations with one site include the Badlands, Wind Cave, Aberdeen, Watertown, Black Hawk, and Brookings.

In 2011, the Sioux Falls SD School Site operated a PM₁₀ monitor but the data was collected under actual conditions and not reference conditions so the data cannot be used to compare to the national PM₁₀ standard. EPA requires that PM₁₀ data be corrected to reference conditions for temperature and pressure. The continuous monitors collecting the PM₁₀, PM_{2.5} and PM_{10-2.5} data was set only to collect data in actual conditions for temperature and pressure. The programming was changed to calculate both actual and reference conditions.

Table 6-1 contains a list of the expected exceedance rate, 2nd highest 24-hour PM₁₀ concentrations, three year average of 2nd highest 24-hour PM₁₀ concentration (design value), and attainment status for the PM₁₀ ambient air monitors throughout the state for calendar year 2009 to 2011. Since the 24-hour standard allows for one expected exceedance per year the 2nd highest

maximum 24-hour concentration helps determine how close a site is to exceeding the 24-hour standard. Using a 3-year average value (design value) reduces the impact from an unusually high concentration in one year and is a better comparison of the actual pollution levels.

Table 6-1 – Statewide PM₁₀ 24-Hour Concentrations

Site	Expected Exceedance Rate	Yearly 2nd Maximum 24-hour	2011 Design Value	Attainment?	Percent Standard
RC Library	0	2009 – 44 ug/m ³ 2010 – 61 ug/m ³ 2011 – 48 ug/m ³	51 ug/m ³	Yes	34%

¹ – Site had a 24-hour PM₁₀ concentration greater than the standard under exceptional event conditions of high winds in 2011.

Figure 6-1 shows a graph of the design value for each PM₁₀ site and is based on the data in Table 6-1. The design value is the calculated average of the yearly 2nd maximum 24-hour average from the most recent consecutive 3-years of data.

Sites with a PM₁₀ design value 80% or greater than the NAAQS have a potential to have a 24-hour sample exceed the PM₁₀ standard. All the site design values for PM₁₀ concentration are all less than 80% of the 24-hour standard as calculated using the data between 2009 and 2011.

Figure 6-1 – 2011 PM₁₀ Design Values Statewide

RC Credit Union Site has the highest PM₁₀ design value in the state at 75% of the standard. The design value dropped slightly by 2% at this site in 2011 compared to the design value in 2010.

The Watertown Site has the next highest design value at 69% of the standard. The design value for this site increased slightly by 3% in 2011 compared to the design value calculated in 2010.

The expected exceedance rates for the 24-hour PM₁₀ standard are calculated using the last 3-years of data. In 2009, one ambient air monitoring site had a 24-hour concentration greater than the PM₁₀ standard. The Wind Cave Site had a concentration of 337 ug/m³. This high concentration was caused by a federal national park prescribed fire and was flagged in EPA's database as an exceptional event. Concurrence from EPA will not be requested on the state's exceptional event flags unless the sampling day will have an impact on the attainment status of the monitoring site.

In 2010, there were no 24-hour PM₁₀ samples that had concentrations greater than the National Ambient Air Quality Standard of 150 ug/m³.

In 2011, two sites had PM₁₀ concentrations greater than the nation standard. Both happened on the same day (October 6, 2011). A high wind event along with very dry soil conditions affected

both sites. The Watertown Site had a 24-hour concentration of 157 ug/m³. The Brookings Site had a 24-hour concentration of 161 ug/m³. The sampling days will affect the attainment status of the Brookings Site so the sampling days were flagged by the department and an exceptional event package is being put together. The department will be requesting EPA's concurrence on the high wind event for both the Brookings and Watertown sites.

Currently, all the sites in South Dakota are attaining the PM₁₀ 24-hour standard.

6.2 Particulate Matter (PM_{2.5})

The PM_{2.5} NAAQS consists of a 24-hour and annual standard. The 24-hour standard is 35 ug/m³. Attainment of the 24-hour standard is achieved when the maximum 24-hour average concentration, based on the annual 98th percentile averaged over three years (24-hour average design value), is less than or equal to 35 ug/m³. The PM_{2.5} annual standard is 15 ug/m³. Attainment is demonstrated when the maximum annual arithmetic mean averaged over three consecutive years (annual design value) is equal to or less than 15 ug/m³.

Spatial averaging of more than one site's annual average is an option when having multiple sites within an area with similar topography and meteorological conditions. The department elected not to do spatial averaging in any of the sampling areas in South Dakota to determine compliance with the annual PM_{2.5} standard.

In 2011, there were eleven PM_{2.5} SLAMS sites operated in the state. Federal Reference Method manual monitors Andersen RASS and Partisol 2000 were operated at six of the PM_{2.5} sites. Met One BAM continuous PM_{2.5} monitors with Federal Equivalent Method designation were operated at six of the sites. One site SD School operates both methods and the remaining five sites have only the Met One BAM continuous PM_{2.5} monitor

6.2.1 PM_{2.5} 24-Hour Standard

Table 6-2 shows the yearly 24-hour 98th percentile for calendar years 2009 to 2011 used in the calculation of the 24-hour design value for PM_{2.5} in 2011, the 24-hour design value, and designation status of each site. In 2011, the highest 24-hour 98th percentile concentration was 23.1 ug/m³ or 66% of the standard and was recorded at the UC #1 Site in Union County on a continuous Met One BAM PM_{2.5} monitor. The site with the second highest 24-hour 98th percentile concentration was at the UC #2 in Union County at 22.1 ug/m³ collected on the Andersen RAAS 100 PM_{2.5} monitor.

Table 6-2 – Statewide PM_{2.5} 24-Hour Concentrations

Site	Yearly 98th Percentile	2011 24-hour Design Value	Attainment Status
RC Library	2009 – 13.1 ug/m ³ 2010 – 20.7 ug/m ³ 2011 – 12.3 ug/m ³	15.4 ug/m ³	Yes
RC Credit Union	2009 – 14.3 ug/m ³ 2010 – 14.0 ug/m ³ 2011 – 13.1 ug/m ³	13.7 ug/m ³	Yes
Badlands	2009 – 10.4 ug/m ³ 2010 – 13.6 ug/m ³ 2011 – 10.0 ug/m ³	11.3 ug/m ³	Yes
SD KELO	2009 – 22.2 ug/m ³ 2010 – 27.8 ug/m ³ 2011 – 21.5 ug/m ³	23.8 ug/m ³	Yes
SD School	2009 – 21.9 ug/m ³ 2010 – 27.9 ug/m ³ 2011 – 21.6 ug/m ³	23.8 ug/m ³	Yes
Brookings	2009 – 25.7 ug/m ³ 2010 – 25.7 ug/m ³ 2011 – 18.4 ug/m ³	23.3 ug/m ³	Yes
Fire Station #1	2009 – 23.0 ug/m ³ 2010 – 26.2 ug/m ³ 2011 – 15.6 ug/m ³	21.6 ug/m ³	Yes
Watertown	2009 – 23.1 ug/m ³ 2010 – 23.9 ug/m ³ 2011 – 18.4 ug/m ³	21.8 ug/m ³	Yes
Wind Cave	2009 – 9.6 ug/m ³ 2010 – 12.4 ug/m ³ 2011 – 11.5 ug/m ³	11.2 ug/m ³	Yes
UC #1	2009 – 21.3 ug/m ³ 2010 – 27.8 ug/m ³ 2011 – 23.1 ug/m ³	24.1 ug/m ³	Yes
UC # 2	2009 – 23.3 ug/m ³ 2010 – 29.7 ug/m ³ 2011 – 22.1 ug/m ³	25.0 ug/m ³	Yes

Figure 6-2 contains a graph of the 24-hour design values for each site. The highest design value was recorded at the UC #2 Site with a concentration of 25.0 ug/m³ or 71% of the standard. UC #1 Site followed closely with a concentration of 24.1 ug/m³. The School and KELO sites in Sioux Falls have the next highest design value at 23.8 ug/m³. As expected, the background sites at Badlands and Wind Cave had the lowest 24-hour design values for PM_{2.5} at 11.3 ug/m³ and 11.2 ug/m³, respectively. All sites had small drops in concentration levels with the addition of the 2011 data and all sites are attaining the 24-hour PM_{2.5} standard.

When using the 98th percentile standard one or two 24-hour PM_{2.5} concentrations greater than the standard at a continuous monitoring site will not affect the 24-hour design value or the area attainment status because the 98th percentile may be the 7th or 8th highest reading for the year. But these concentrations may affect the annual design value and need to be considered when evaluating the data results for each year. A conceptual theory on what caused the high concentrations can be formed and further developed in future years. In some cases if local sources are causing the problem early actions can be taken to reduce concentration levels and further protect public health from high levels of PM_{2.5}.

Figure 6-2 – 2011 PM_{2.5} Statewide 24-Hour design values

In 2009, there was an event in eastern South Dakota which affected all six sites. The conception theory on what caused the high concentrations is long range transport of PM_{2.5} pollution from high population centers east and southeast of Minnesota and Iowa with increases in levels caused by meteorological conditions, heavy fog, that did not allow dispersion of the pollutants.

In 2010, two events recorded 24-hour PM_{2.5} concentrations greater than 35 ug/m³ at different monitoring sites. The first event occurred from October 20 to October 23 when a federal prescribed fire burned the area near the Wind Cave Site. This is the second time in two years that a prescribed fire caused high PM_{2.5} concentrations. Concentrations during the first day of the event were 115.0 ug/m³ on the continuous monitor and 111.8 ug/m³ on the manual monitor. On the second day of the fire, the PM_{2.5} concentration was 54.5 ug/m³ on the continuous monitor. On the following days concentrations were below the standard and continued to move lower until the fire burned out. Both days with PM_{2.5} concentrations over the standard were flagged as exceptional events due to a federal prescribed fire.

The department will request EPA's concurrence flag for these days if they will have a significant impact on the attainment status of this site. This event is not expected to re-occur because the

department is working with the federal land managers on a Smoke Management Plan as part of the Regional Haze Program to minimize the impacts of federal prescribed fires in South Dakota.

The second event in 2010 with PM_{2.5} concentrations greater than the standard occurred on February 5 and 6 on the eastern edge of the state. An alert notice was issued by Minnesota and Iowa because meteorological conditions were expected to increase pollution levels and transport PM_{2.5} air pollution into the region. The Minnesota alert notice indicated the high concentration levels were an artifact from long range transport of PM_{2.5} air pollution to the east and southeast. The weather during this period of time included light winds and fog with snow on the ground which further reduces the dispersion of PM_{2.5} pollutants.

On February 5 all three continuous PM_{2.5} monitor sites on the southeastern corner of the state had concentrations over the standard. UC #1 had the highest concentration at 46.1 ug/m³ followed close by SD School and UC #2 in the lower 40 ug/m³ range. On February 6 only UC #1 had a concentration over the standard at 36.2 ug/m³. SD School and UC #2 had concentrations just under the standard. The other sites in the eastern half of the state are on an every third day schedule and did not have samples for these days.

During 2011, none of the monitoring sites had a concentration greater than the 24-hour PM_{2.5} standard. The highest 24-hour PM_{2.5} concentrations were recorded in the southeast part of the state. On March 8, 2011, the continuous PM_{2.5} monitors at SD School, UC #1 and UC #2 had concentrations in the low 30 ug/m³ range. Just as in 2009 and 2010 the high PM_{2.5} levels were high over a large part of southeastern South Dakota. Once again it was associated with high concentrations in Iowa and Minnesota pointing to long range transport of air pollution.

6.2.2 PM_{2.5} Annual Standard

Table 6-3 contains a list of the annual averages, annual design values and attainment status for each of the PM_{2.5} sites using the data from 2009 to 2011 in the state. The highest annual average concentration in 2011 was recorded at the UC #1 Site at 9.3 ug/m³. The second highest annual concentration was at the SD School Site with an annual average of 8.8 ug/m³. The Badlands Site had the lowest annual average at 3.5 ug/m³ in 2011, slightly lower than in 2010.

Table 6-3 – Statewide PM_{2.5} Annual Concentrations

Site	Annual Averages	2011 Annual Design Values	Attainment Status
RC Library	2009 – 5.9 ug/m ³ 2010 – 6.6 ug/m ³ 2011 – 5.4 ug/m ³	6.0 ug/m ³	Yes
RC Credit Union	2009 – 6.7 ug/m ³ 2010 – 6.6 ug/m ³ 2011 – 4.5 ug/m ³	5.3 ug/m ³	Yes
Badlands	2009 – 4.0 ug/m ³ 2010 – 3.9 ug/m ³ 2011 – 3.5 ug/m ³	3.8 ug/m ³	Yes

Site	Annual Averages	2011 Annual Design Values	Attainment Status
KELO	2009 – 9.1 ug/m ³ 2010 – 9.2 ug/m ³ 2011 – 8.7 ug/m ³	9.0 ug/m ³	Yes
SD School	2009 – 9.0 ug/m ³ 2010 – 9.7 ug/m ³ 2011 – 8.8 ug/m ³	9.2 ug/m ³	Yes
Brookings	2009 – 8.6 ug/m ³ 2010 – 8.6 ug/m ³ 2011 – 7.9 ug/m ³	8.4 ug/m ³	Yes
Aberdeen	2009 – 8.1 ug/m ³ 2010 – 8.7 ug/m ³ 2011 – 7.1 ug/m ³	8.2 ug/m ³	Yes
Watertown	2009 – 8.5 ug/m ³ 2010 – 8.9 ug/m ³ 2011 – 8.1 ug/m ³	8.5 ug/m ³	Yes
Wind Cave	2009 – 4.7 ug/m ³ 2010 – 4.7 ug/m ³ 2011 – 3.7 ug/m ³	4.8 ug/m ³	Yes
UC #1	2009 – 7.4 ug/m ³ 2010 – 9.6 ug/m ³ 2011 – 9.3 ug/m ³³	8.8 ug/m ³	Yes
UC #2	2009 – 8.4 ug/m ³ 2010 – 9.6 ug/m ³ 2011 – 8.2 ug/m ³	8.9 ug/m ³	Yes

Figure 6-3 contains a graph of the PM_{2.5} annual average design value for each site. None of sites in the network had a 2011 design value that exceeded the annual PM_{2.5} standard. The 2011 annual design value for each site followed the same pattern as the 24-hour levels. The highest design values occur in the eastern third of the state. The highest annual design value occurred at the SD School Site with a level of 9.2 ug/m³ which is 61% of the annual standard. The lowest PM_{2.5} annual design value occurred at the Badlands Site with a concentration of 3.8 ug/m³ which is 11% of the annual standard.

Figure 6-3 – 2011 PM_{2.5} Statewide Annual Design Values

6.3 Lead

During the early 1980's, the department conducted lead sampling. The levels detected were well below the NAAQS levels at that time. After passage of the 1990 Clean Air Act Amendments, there were concerns with the way EPA had instructed states in determining if those areas were in attainment of the lead standard. For this reason, a monitoring site was established in April 1992, at the Jaehn's Site in Rapid City to determine compliance with the standard. This site was downwind of GCC Dacotah, which is a cement plant that burns coal and has the potential to emit lead. The results of the analyzed data from the second quarter of 1992 through the first quarter of 1994 showed lead levels well below the NAAQS. Due to the low concentrations of lead in Rapid City, the sampling site was terminated at the end of the first quarter in 1994.

EPA changed the lead NAAQS on October 15, 2008. The change significantly lowers the lead standard from 1.5 ug/m³ to 0.15 ug/m³ based on the annual maximum three month rolling average. Attainment of the lead NAAQS is achieved if the annual maximum three month rolling average, averaged over a three year period, is less than or equal to 0.15 ug/m³.

In 2010, EPA completed a rule change that requires source type testing in addition to network testing if a source has emissions of 0.5 tons or greater per year. The rule originally required lead testing at the NCore Site. The final rule required lead testing at NCore Site only if the site is located in city with a 500,000 and greater population. None of the facilities in the South Dakota emissions inventory have lead emissions at or greater than 0.5 tons per year so no source related testing is required at this time. The NCore site is located in Sioux Falls and the city has a population under 500,000 so no testing is required. Currently, there are no lead sampling sites planned for South Dakota because of the low potential for concentrations of lead pollution.

The lead sampling in the past indicates that South Dakota is attaining the new lead standard.

6.4 Ozone

In 1999, the first ozone monitor was setup in South Dakota and was located at the Sioux Falls Hilltop Site. In 2000, a second ozone monitor was added at the Robbinsdale Site in Rapid City. In 2005, the Rapid City ozone monitoring site was moved to the RC Credit Union Site because of the planned move of the Robbinsdale sampling shelter to the Wind Cave Site.

In 2003, the National Parks Service added an ozone monitor to the Badlands Site. It is located in a shelter next to the IMPROVE monitors near the park visitor center/headquarters.

In 2005, a fourth ozone site was added at the Wind Cave Site. The Wind Cave Site was added to determine if a large increase in oil and gas mining in Colorado, Wyoming and Montana would cause impacts on the Wind Cave National Park, which is a Class I area.

Air dispersion modeling results completed by the department showed the RC Credit Union Site does not meet location requirements in 40 CFR Part 58 because it is located in the middle of the one microgram impact area for nitrogen dioxide from industrial sources in Rapid City. For this reason the ozone analyzer was moved from the RC Credit Union Site to the Black Hawk Site in 2007.

Beginning in 2008, the Hilltop Site had to be moved and a new location was found at the School for the Deaf campus. The move to a new location was required because the city of Sioux Falls had to revert the Hilltop property back to the original owner when the water tower system was replaced ending the agreement to use the property. Also in 2008, a site was added north of Brookings at the Research Farm.

In 2008, EPA adopted a new ozone standard at 0.075 parts per million. The form of the standard remained as the fourth highest, daily 8-hour average, averaged over three years (ozone design value). In 2011, EPA implemented the 0.075 part per million national standard. EPA is also completing a 5-year review of the ozone standard 2012. The 2011 design value in parts per million for each of the sites can be seen in Table 6-4 and Figure 6-4.

Table 6-4 – Statewide Ozone 4th highest Concentrations

Site	4 th Highest Concentration	3-year Average	Attainment Status
SD School	2009 – 0.062 ppm 2010 – 0.064 ppm 2011 – 0.065 ppm	0.064 ppm	Yes
Research Farm	2009 – 0.057 ppm 2010 – 0.064 ppm 2011 – 0.064 ppm	0.062 ppm	Yes
Black Hawk	2009 – 0.057 ppm 2010 – 0.057 ppm 2011 – 0.057 ppm	0.057 ppm	Yes

Site	4 th Highest Concentration	3-year Average	Attainment Status
Badlands	2009 – 0.054 ppm 2010 – 0.058 ppm 2011 – 0.052 ppm	0.055 ppm	Yes
Wind Cave	2009 – 0.061 ppm 2010 – 0.059 ppm 2011 – 0.060 ppm	0.060 ppm	Yes
UC #3	2009 – 0.060 ppm 2010 – 0.062 ppm 2011 – 0.062 ppm	0.061 ppm	Yes

In 2011, the SD School Site had the highest 3-year average ozone concentrations in the state at 0.064 ppm, which is 85% of the 2008 revised ozone standard. The SD School Site replaced the Wind Cave Site as the state's highest concentration site for the first time in 2010 and continues as the highest ozone site in the state. The second highest location is Research Farm Site at 0.062 ppm also located in the eastern edge of the state. Since 2008, both the Wind Cave and Badlands sites are reporting significantly lower ozone design values with the Badlands now the lowest site in the state.

Currently all ozone sites are at or less than 85% of the standard at the end of 2011. The data collected in the past three years demonstrates that South Dakota is attaining the national ozone standard. Ozone concentrations are near the same concentration level statewide.

Figure 6-4 – 2011 Ozone Design Values Statewide

6.5 Sulfur Dioxide

Five sulfur dioxide ambient air monitoring sites were operated in 2010. The analyzers were located at SD School, Badlands, RC Credit Union, UC #1, and UC #2 sites. EPA made a major change to the sulfur dioxide standard in 2009 replacing the 24-hour and annual primary standard with a new 1-hour standard. The 1-hour sulfur dioxide standard concentration is 75 parts per billion (ppb) based on the three year average of the yearly 99th percentile level (1-hour design value). The 3-hour secondary standard for sulfur dioxide was maintained without change.

6.5.1 Sulfur Dioxide 1-Hour Standard

Table 6-5 contains the yearly 99th percentile concentration, the 1-hour design value, and the attainment status for each site. The site sulfur dioxide design values are based on sulfur dioxide data collected in 2009 to 2011. The highest 99th percentile 1-hour level in 2011 was recorded at the UC #2 Site at 8.4 ppb. The RC Credit Union Site had the second highest 1-hour concentration at 8.2 ppb. The SD School Site had a significant decrease in sulfur dioxide concentrations over the last three years moving from 10 to 4.6 ppb.

Table 6-5 – 2011 Statewide Sulfur Dioxide 1-hour Design Values

Site	99 th Percentile Concentration	3-year Average	Attainment Status
SD School	2009 – 10.0 ppb 2010 – 5.0 ppb 2011 – 4.6 ppb	6.4 ppb	Yes
RC Credit Union	2009 – 2010 – 2011 – 8.2 ppb	8.2 ppb	¹
Badlands	2009 – 5.0 ppb 2010 – 9.0 ppb 2011 – 5.9 ppb	6.6 ppb	Yes
UC #1	2009 – 9.6 ppb 2010 – 11.5 ppb 2011 – 6.5 ppb	9.2 ppb	Yes
UC #2	2009 – 6.0 ppb 2010 – 8.6 ppb 2011 – 8.4 ppb	7.7 ppb	Yes

¹ – Site with less than three years of air monitoring data. The department is unable to compare the results to the sulfur dioxide 1-hour standard until three years of data is obtained.

Figure 6-5 shows the three year average of the yearly 99th percentile 1-hour concentration for each of the sites in the network for 2011. All five of the sites recorded concentrations well under the 1-hour standard. The highest 1-hour design value was recorded at the UC #1 Site with a maximum concentration of 9.2 ppb which is 12% of the standard. The second highest was recorded at the UC #2 Site with a concentration of 7.7 ppb which is 11% of the standard. The data collected in the past three years demonstrates that South Dakota is attaining the new 1-hour sulfur dioxide standard.

Figure 6-5 – 2010 Sulfur Dioxide 1-Hour Concentrations

* – RC Credit Union Site has less than three years of air monitoring data. The department is unable to compare the results to the 1-hour sulfur dioxide standard until three years of data is obtained.

6.5.2 Sulfur Dioxide 3-Hour Secondary Standard

The secondary sulfur dioxide standard is based on a 3-hour average concentration of 0.500 ppm, not to be exceeded more than once per year. The graph in Figure 6-6 shows the second maximum 3-hour concentrations for five sites in the network in 2011. The 3-hour sulfur dioxide concentrations for all of the sites are very low. The Badlands and UC #2 site recorded the highest 3-hour average in 2011 with a concentration of 0.006 ppm at 1% of the 3-hour standard. RC Credit Union and UC #1 sites had the second highest 3-hour concentration at 0.005 ppm at 1% of the standard.

Figure 6-6 – 2011 Sulfur Dioxide 3-hour Concentrations

The data collected in 2011 demonstrates that South Dakota is attaining the 3-hour secondary standard for sulfur dioxide. Concentrations at the monitoring sites are very low near the detection level of the analyzer.

6.6 Nitrogen Dioxide

Beginning in 2010 the standard for nitrogen dioxide was revised by adding a 1-hour standard of 100 ppb and keeping the annual arithmetic mean standard of 53 ppb. Attainment is demonstrated when the 3-year average of 98th percentile daily maximum 1-hour concentration is less than or equal to 100 ppb (1-hour design value) and the annual arithmetic mean is less than or equal to 53 ppb (annual design value).

There were five nitrogen dioxide ambient air monitoring sites operated in 2011. The locations were at the SD School, Badlands, RC Credit Union, UC #1, and UC #2 sites.

6.6.1 Nitrogen Dioxide 1-Hour Standard

Table 6-6 contains the 1-hour 98th percentile concentration for each of the last three years, 1-hour design values, and the attainment status for each site. The RC Credit Union Site had the highest yearly 98th percentile 1-hour concentration at 47 ppb in 2011. The second highest 1-hour was recorded at the SD School Site at 39 ppb.

Table 6-6 – Nitrogen Dioxide 1-hour 98th Percentile Concentrations

Site	98th Percentile Concentration	3-year Average	Attainment Status
SD School	2009 – 38 ppb 2010 – 48 ppb 2011 – 39 ppb	42 ppb	Yes
Badlands	2009 – 4 ppb 2010 – 5 ppb 2011 – 4 ppb	4 ppb	Yes
RC Credit Union	2009 – 2010 – 2011 – 47 ppb	47 ppb	¹
UC #1	2009 – 17 ppb 2010 – 22 ppb 2011 – 15 ppb	18 ppb	Yes
UC #2	2009 – 16 ppb 2010 – 20 ppb 2011 – 14 ppb	17 ppb	Yes

¹ – Site with less than three years of air monitoring data. The department is unable to compare the results to the nitrogen dioxide 1-hour standard until three years of data is obtained.

Figure 6-7 shows the nitrogen dioxide 1-hour design values for each of the sites with three years of data. The RC Credit Union Site had the highest concentration but only has one year of data. SD School Site recorded the next highest 1-hour nitrogen dioxide design value at 42 ppb or 42% of the standard. Most of the hourly concentrations collected at the five sites are at the detection level of the analyzers. In general the rural areas have concentrations near the detection level. Rural areas impacted by a large source of nitrogen dioxide emissions like at UC #1 and UC #2 record higher concentrations than background sites but the levels are still well under the standard.

All sites had concentrations under the 1-hour nitrogen dioxide standard and are attaining the standard using data from 2009 to 2011.

Figure 6-7 – 2011 Nitrogen Dioxide 1-hour Design Values

* - RC Credit Union Site has less than three years of air monitoring data. The department is unable to compare the results to the 1-hour nitrogen dioxide standard until three years of data is obtained.

6.6.2 Nitrogen Dioxide Annual Standard

Figure 6-8 shows the annual average for the five sites operated in 2011. The highest nitrogen dioxide annual average was recorded at the UC #2 Site at 8.4 ppb at 16% of the standard. The Badlands Site remained at about same level near the detection concentration level. In 2011, all five sites attained the annual standard for nitrogen dioxide.

Figure 6-8 – 2011 Nitrogen Dioxide Annual Concentration

6.7 Carbon Monoxide

The carbon monoxide standard is based on two primary standards in the form of a one-hour and 8-hour average concentration. The department started the operation of the first carbon monoxide analyzer in January of 2010 at UC #1 Site in Union County. A second analyzer was added to the SD School Site as required by the National Core sampling requirements and began testing at the start of 2011.

The one-hour standard is 35.0 ppm and is not to be exceeded more than once per year. The highest 1-hour concentration of carbon monoxide recorded at the SD School Site was 1.4 ppm in 2011. Figure 6-9 shows the carbon monoxide 1-hour maximum concentrations for both sites.

Figure 6-9 – Carbon Monoxide 1-Hour Concentration

The other standard is an 8-hour average concentration of 9.0 ppm, not to be exceeded more than once per year. The highest 8-hour average recorded at the SD School Site was 0.9 ppm in 2011. The carbon monoxide concentrations are very low at both sites and even though the sites do not have three years of data yet, the department anticipates that these areas are attaining the NAAQS. Figure 6-10 shows the carbon monoxide maximum 8-hour average concentrations for both sites.

The data at UC #1 represents background levels of carbon monoxide collected in a rural area in eastern South Dakota. It is anticipated by the department that carbon monoxide levels at UC #1 represent one of the higher concentration locations for a rural area given the traffic counts on Interstate 29 near the sampling site. Other rural areas with less traffic emissions could have even lower concentrations.

The carbon monoxide concentrations at the SD School Site represent urban areas being collected in an area that has some of the highest traffic counts in the state.

Figure 6-10 – Carbon Monoxide 8-Hour Average Concentration

7.0 AIR MONITORING SITE EVALUATION AND TRENDS

This section will discuss the goals of each air monitoring site in the network and trends for each pollutant. Through this evaluation a determination is made if site goals are being met and if each testing parameter is needed at the site. This section also has site specific information tables including AQS ID #, location, operation, data use, sampling schedule, monitoring objectives, spatial scale, and sampling and analytical methods required as part of the annual plan requirements in 40 CFR Part 58.

7.1 Rapid City Area

The Rapid City area had a total of three monitoring sites collecting data in 2011. The high concentration site for PM₁₀ was located at the RC Credit Union Site and a continuous PM₁₀ monitor was used to determine compliance with the NAAQS standards. The RC Library and RC National Guard sites have manual Andersen PM₁₀ monitors collecting 24-hour data using a filter based gravimetric sampling method.

In cooperation with the City, County, and industry, the department is implementing a Natural Events Action Plan for the Rapid City area. Part of this plan is to alert the public of the potential of high dust levels caused by high winds and to advise the public of precautions to take during the high wind events. Under this plan high wind dust alerts are called when the following forecast conditions occur:

1. Hourly wind speeds exceed 20 miles per hour;
2. Peak wind gusts are greater than 40 miles per hour; and
3. Five consecutive days of 0.02 inches or less of precipitation each day excluding dry snow.

During 2011, a total of seven high wind dust alerts were called for the Rapid City area. None of the days exceeded the PM₁₀ 24-hour standard. The highest 24-hour average concentration recorded during an alert was on September 12, 2011 at 117.4 ug/m³. This demonstrates the implementation of the Natural Events Action Plan for the Rapid City area is working to maintain PM₁₀ concentrations below the NAAQS during high wind events.

The Rapid City area had two monitoring sites collecting data for PM_{2.5} in 2011. The Library Site has manual Andersen PM_{2.5} monitors collecting 24-hour data using a filter based gravimetric sampling method. A continuous Met One BAM PM_{2.5} monitor was operated on the RC Credit Union Site.

In the fall of 2008, a surface water quality problem was found when Rapid Valley began using Rapid Creek for a drinking water source. Testing indicated high levels of chlorides during snow melt events caused the drinking water to smell and the water treatment plant had to stop producing drinking water until chloride levels dropped. Testing indicated liquid deicer used on the streets during snow and ice events was causing the problem. The city of Rapid City began a process of reducing the use of liquid deicer and increasing the use of river sand in the eastern and south eastern parts of Rapid City to help reduce chloride levels in Rapid Creek. The department is working with Rapid City to determine which streets can be changed from chemical deicer to sand so air quality levels have not been affected.

One dust complaint was received by the Rapid City Area Air Quality Program during the winter of 2011/2012. The complaint indicated general dusty conditions in North Rapid City area along Haines Avenue. A follow-up by Rapid City Air Quality staff indicated dusty conditions in this area of the city caused by the drying out of sanding material and dirt track out in early spring. PM₁₀ concentrations were less than 50% the standard during the months of January, February and March of 2012.

7.1.1 RC Library Site

The RC Library Site is located on the library building in Rapid City. The site was established in 1972, and it is the oldest sampling site in South Dakota still operating. The site is geographically located in the downtown area of the city east of the hogback and in the Rapid Creek river valley. The site purpose is to evaluate population exposure, fugitive dust controls, the success of the street sanding and sweeping methods employed by the city of Rapid City and general concentration levels in the eastern part of the city. Figure 7-1 shows a picture of the RC Library Site.

Figure 7-1 – RC Library Site

PM₁₀ sampling began at the site in 1985. PM_{2.5} monitors were added to the site in 1999. An attainment designation for PM_{2.5} was completed for the Rapid City area in 2004. An attainment designation for PM₁₀ was completed and approved by EPA for the Rapid City area in 2006. Table 7-1 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Analysis Methods	Gravimetric
Data Use	SLAMS (Comparison to the NAAQS)

7.1.1.1 RC Library Site – PM₁₀ Data

Annual average PM₁₀ concentrations for the RC Library Site are shown in Figure 7-2. The PM₁₀ concentrations show a gradual decline from a high of 30 ug/m³ in 1991, to a low of 16 ug/m³ in 2005. The largest reduction in annual concentrations came when changes were implemented by the city on the street sanding and sweeping operations in the early 1990s. In the last six years, annual concentrations have leveled off and are almost steady with a 1 or 2 ug/m³ change per year. The plan is to continue the PM₁₀ monitoring because this is the only site east of the hogback in Rapid City and the site will provide a check on PM₁₀ levels as the city of Rapid City adjusts its sanding techniques in eastern Rapid City.

Figure 7-2 – RC Library Site – PM₁₀ Annual Averages

7.1.1.2 RC Library Site – PM_{2.5} Data

The graph in Figure 7-3 shows the PM_{2.5} annual average for each sampling year since 2001. The highest annual average was 7.8 ug/m³ in 2001 and the lowest was 5.4 ug/m³ in 2011. The annual average concentrations vary in difference from the highest to lowest annual average by 2.4 ug/m³. The trends indicate a declining PM_{2.5} concentration level for the past five years with

2011 recording the lowest annual average PM_{2.5} concentration for this site. Plans are to continue testing for PM_{2.5} at this site.

Figure 7-3 – RC Library Site PM_{2.5} Annual Averages

7.1.2 RC National Guard Site

The RC National Guard Site is located on the roof of the armory at the Camp Rapid facility in western Rapid City (see Figure 7-4). The site was established at this location in 1992, with PM₁₀ the only sampling parameter because a large portion of the particulate matter emissions near this site consists of crustal material. Because the site is located only a few blocks from the high concentration location at the RC Credit Union Site, the site is designated as a SPM site for PM₁₀. The goal of the site is to determine the size of the area being impacted by fugitive dust sources in the quarry area in western Rapid City.

In the spring of 2009 a radiation monitor was added to the site as part of the national RadNet network of sites. The monitor is a SPM site that provides a warning system to detect levels of radiation from accidental releases or military activities emitting radiation.

Figure 7-4 – RC National Guard Site

The sampling objectives for the PM₁₀ parameter is to measure population exposure and high concentration from source impacts from the quarry area north of the monitoring site. In addition, this monitoring site along with the RC Credit Union Site, define the high PM₁₀ concentration area in western Rapid City. Table 7-2 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Table 7-2 – RC National Guard Site Specifics

Data Use	SPMS (No comparison to the NAAQS),

7.1.2.1 RC National Guard Site PM₁₀ Data

The RC National Guard Site is the second oldest monitoring location in Rapid City and is a special purpose monitoring site sampling for PM₁₀. The graph in Figure 7-5 shows the annual means for the site since 1992. The annual means vary from a high of 41 ug/m³ in 1997 to a low of 24 ug/m³ in 2011. The trends for the annual mean concentrations continue to decline, but do cycle up and down from year to year. The annual average concentration in 2011 is the lowest recorded at this site.

Figure 7-5 – RC National Guard PM₁₀ Annual Averages

The RC Credit Union Site is only four city blocks from the RC National Guard Site. The RC National Guard Site's PM₁₀ concentrations continue to be well below the levels recorded at the RC Credit Union Site but still is an indication how levels decline as the distance from the source increases. Therefore, the RC National Guard Site PM₁₀ testing will continue to be operated.

7.1.3 RC Credit Union Site

The RC Credit Union Site is located on a lot next to Fire Station #3 building. The RC Credit Union Site replaced the Fire Station #3 Site in October 2003 and is the high PM₁₀ concentration location for the western part of Rapid City. The RC Credit Union Site is located just south of the quarry area and is centrally located in relation to the quarry facilities. Figure 7-6 contains a picture of the monitoring site looking in a north direction towards the quarry area. The goal of this site is to determine if the Rapid City area is attaining the PM₁₀ standard and population exposure.

Figure 7-6 – RC Credit Union Site

Continuous Thermo BETA PM₁₀ continuous and Met One BAM PM_{2.5} monitors were operated at this site in 2011. The BETA PM₁₀ monitor provides hourly concentrations on an everyday sampling schedule. The hourly readings from the continuous PM₁₀ monitor are used to assist in the calling of high wind dust alerts for Rapid City and to compare concentrations to the PM₁₀ NAAQS.

A continuous Met One BAM PM_{2.5} monitor is used to supply hourly data for investigation of high concentration days and to compare to the PM_{2.5} standards. Table 7-3 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

In 2011, continuous SO₂ and NO₂ analyzers were added to the RC Credit Union Site to provide data on population exposure and source oriented testing near the facilities in the quarry area.

7.1.3.1 RC Credit Union Site – PM₁₀ Data

The RC Credit Union Site began operation in October of 2003. Only three months of data was collected in 2003, so 2004 is the first complete sampling year. Figure 7-7 shows a graph of the annual average PM₁₀ concentration.

The PM₁₀ annual average concentration shows a declining level each year since 2004. In 2011, average concentration levels increased back to the level in 2009. Over the seven year period, annual concentrations changed significantly by 16.0 ug/m³. Testing for PM₁₀ concentrations is a priority for this site and the parameter will be continued.

Figure 7-7 – RC Credit Union Site PM₁₀ Annual Averages

7.1.3.2 RC Credit Union Site PM_{2.5} Data

The testing for PM_{2.5} parameter using the manual method began at this site in October 2003 and completed the first full year of testing in 2004. The RC Credit Union Site records the highest PM_{2.5} concentrations in the Rapid City area for both 24-hour and annual concentrations using the manual FRM monitor.

In 2009, a continuous method PM_{2.5} monitor was added to the site as a special purpose monitor. The continuous monitor being a new method EPA allows the operate of the monitor as a special purpose method for up to three years before the data from the monitor is required to be compared to the PM_{2.5} standard. By the end of 2011 the continuous monitor had operated for three years. As a cost savings change the manual PM_{2.5} monitor was removed and the continuous monitor became the SLAMS monitor providing more data at a lower cost per year of operation.

Figure 7-8 shows the annual average for each sampling year since 2009 when the continuous monitor was setup. The annual average concentrations have remained relatively constant over the first four years. But in the last four years PM_{2.5} annual concentrations have declined to the lowest level since the site began operation with a concentration of 4.5 ug/m³ for the annual average. The highest annual average for PM_{2.5} at this site was 6.1 ug/m³ in 2009. Over the three year period, annual concentrations changed by 1.6 ug/m³.

Figure 7-8 – RC Credit Union Site PM_{2.5} Annual Averages

The parameter of PM_{2.5} will be continued at this site using the continuous monitor to determine compliance with the NAAQS and to determine any change in concentration levels.

7.2 RC Credit Union Site Sulfur Dioxide

Testing for sulfur dioxide started at the beginning of 2011 for this site. Some testing for the parameters was done in the 1990s but that data is old and there is need for the collection of new data. The annual standard for sulfur dioxide was dropped when the standard was revised so the 1-hour 99 percentile concentrations will be used to track trends.

See Figure 7-9 for the 2011 concentration for sulfur dioxide at the RC Credit Union Site. The concentration is low only 11% of the standard. Testing for sulfur dioxide will continue at this site until at least three years of data is collected.

7.3 RC Credit Union Site Nitrogen Dioxide

Testing for nitrogen dioxide started at the beginning of 2011 for this site. Some testing for the parameters was done in the 1990s but that data is old and there is need for the collection of new data. The nitrogen dioxide standard includes a 1-hour and annual average concentrations so the annual will be represented to track trends.

See Figure 7-10 for the 2011 concentration for nitrogen dioxide at the RC Credit Union Site. The concentration is low only 15% of the standard. Testing for nitrogen dioxide will continue at this site until at least three years of data is collected.

Figure 7-9 –RC Credit Union Site Sulfur Dioxide 1-hour Averages

Figure 7-10 – RC Credit Union Site Nitrogen Dioxide Annual Averages

7.3 Black Hawk Site

Black Hawk is a small town located just north of Rapid City in Meade County north of the quarry area. Black Hawk is not an incorporated city but is a growing subdivision and is part of the Rapid City MSA. The goal of the Black Hawk Site is to determine urban background concentrations for PM₁₀ coming into the Rapid City area from the north and determine compliance with the ozone NAAQS in the Rapid City MSA.

The Black Hawk Site was setup in the fall of 2000. The site is located on a small hill east of the Black Hawk Elementary School. PM₁₀ and PM_{2.5} monitors were located on a sampling shelter until October 2003 when the sampling shelter was moved to the RC Credit Union Site. The monitors were then located on scaffolding within a fenced area until the fall of 2006 when a shelter was added back to the site.

At the end of 2004 the PM_{2.5} monitors were removed because concentrations were the lowest in the area and the potential for concentrations over the NAAQS were very low. In 2007, the ozone analyzer was moved from RC Credit Union Site to the Black Hawk Site to operate the ozone parameter outside of the modeled one microgram nitrogen dioxide influence area from air quality sources in western Rapid City. See Figure 7-11 for a current picture of the site looking to the northwest.

Figure 7-11 – Black Hawk Site

The land use around the site is mainly residential with a few service type businesses. There are no obstructions around the monitoring site. The limestone quarry industries are located to the south and southeast of the Black Hawk Site and are expanding to ore bodies located closer to this site. The first of the new limestone quarries are currently operating about one mile south of the site.

The site's spatial scale is neighborhood for PM₁₀ and ozone sampling. The objectives of the PM₁₀ sampling are high concentration, population, and source impact. The objectives of the ozone sampling are high concentration and population. The goals are being met and the site will be continued with sampling for both ozone and PM₁₀ parameters. Table 7-4 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Table 7-4 – Black Hawk Site Specifics

7.3.1 Black Hawk Site – PM₁₀ Data

Figure 7-12 contains a graph showing the PM₁₀ annual averages for the Black Hawk Site. The first four years of PM₁₀ concentration levels remained about the same. In 2005, the annual average dropped significantly by approximately 4 ug/m³ from the 2004 level. The highest annual average was 21 ug/m³ recorded in both 2001 and 2003. The lowest level of 12 ug/m³ was recorded in 2011. In 2011, the PM₁₀ concentrations dropped 2 ug/m³ from the concentration in 2010. The overall trend shows a significant decrease in concentrations over the eleven year period.

Figure 7-12 – Black Hawk Site – PM10 Annual Averages

7.3.2 Black Hawk Site – Ozone Data

The 2011 sampling year is the fourth ozone season at the Black Hawk Site (see Figure 7-13). In the first year of testing (2008), the site recorded the second highest ozone level in the state. In 2009 to 2011, the ozone levels are slightly less than the 2008 ozone level but appear to have flattened out.

Figure 7-13 – Black Hawk Site Ozone Yearly 4th Highest 8-hour Averages

The testing results show the area is attaining the ozone standard. Plans are to continue to test for ozone at this location.

7.4 Badlands Site

The Badlands is one of two Class I areas in South Dakota designated for visibility protection under the Clean Air Act. The Badlands area is a large national park that attracts more than two million visitors each year. The Badlands area is a dry semi-desert area with short prairie grass and beautiful sandstone cliff vistas.

The Badlands Site was established in 2000, with manual monitors for PM_{10} and $PM_{2.5}$. The site is located next to the IMPROVE site which also included an ozone analyzer operated by the National Park Service. The site is in the southeast part of the park near the visitor center. Figure 7-14 shows a current picture of the Badlands Site.

In October of 2004, the number of pollutant parameters was increased by adding continuous monitors for PM_{10} , $PM_{2.5}$, sulfur dioxide, and nitrogen dioxide. The changes increased the amount of data collected and provide additional information on transport of air pollution. At the end of 2007, the department took over the operation of the ozone monitor at this site upon a request made by the National Park Service.

Figure 7-14 –Badlands Site

The IMPROVE data is used to determine what type of sources are impacting the visibility of the national parks in South Dakota. The goal of having a SLAMS site next to the IMPROVE site is

to determine how the data compares between the two different sampling methods, to determine air pollution background levels, and to see if pollution trends show long range transport of air pollution into the state. Table 7-5 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

7.4.1 Badlands Site – PM₁₀ Data

PM₁₀ data has been collected at this site since 2000. The PM₁₀ manual monitor was operated on an every sixth day schedule through 2004. Beginning in 2005, a continuous Thermo Beta Gauge PM₁₀ monitor replaced the manual monitors.

Figure 7-15 contains a graph of the annual averages for the Badlands Site. The annual average concentration over the last seven years varied slightly overall. The highest annual average concentration of 12 ug/m³ was recorded in 2007. The lowest annual average concentration of 7 ug/m³ was recorded in 2009. The PM₁₀ concentrations recorded at this site are some of the lowest levels in the state and are considered background for the western half of the state. This parameter is meeting the goals for testing at this site and will be continued.

Figure 7-15 – Badlands Site – PM₁₀ Annual Averages

7.4.2 Badlands Site – PM_{2.5} Data

The PM_{2.5} monitors run on an every third day schedule from 2001 to 2008. With the completion of the 2003 year, the site had three years of PM_{2.5} data and the department was able to make a comparison of the concentration levels to the 24-hour and annual standards. The area was designated as attaining the standard. Beginning in 2009, the Met One BAM-1020 FEM replaced the manual RAAS 100 and the sampling schedule went to every day providing hourly and 24-hour average concentrations.

The annual averages for the Badlands Site show a concentration range with a high of 5.8 ug/m³ in 2003 and a low of 3.5 ug/m³ in 2011. The trend for the annual average was steady during the first eight years of testing but has declined slightly in the last three years by 1.7 ug/m³. PM_{2.5} concentrations at this site are the lowest in the state and represent background levels for western South Dakota. Figure 7-16 contains a graph of the annual averages. This parameter is meeting the goals for testing at this site and will be continued.

Figure 7-16 – Badlands Site PM_{2.5} Annual Averages

7.4.3 Badlands Site – Sulfur Dioxide Data

The first year of testing at the Badlands Site for sulfur dioxide occurred in 2005. As expected, concentrations for sulfur dioxide are very low and represent background levels. Concentrations are at or near the detection limit for the analyzers at 0.1 ppb for the annual average levels for sulfur dioxide.

In 2011, the annual average was down slightly from 2010 from 3.3 ppb to 1.6 ppb of sulfur dioxide. See Figure 7-17 to view a graph of the annual average concentrations for sulfur dioxide. The linear trends line shows a steady to slight decrease in concentrations but levels are very low

and indicate minimal concentrations of sulfur dioxide. This parameter is meeting the goals for testing at this site and will be continued.

Figure 7-17 – Badlands Site Sulfur Dioxide Annual Averages

7.4.4 Badlands Site – Ozone Data

The first year of testing at the Badlands Site for ozone with the equipment being operated by the National Park Service was 2003. The department completed quarterly audits of the ozone analyzer so data could be compared to the NAAQS. At the beginning of 2008 sampling year, the department took over the operation of the ozone analyzer.

Concentrations of ozone at this site have varied over the seven years of testing. The yearly 4th highest 8-hour average ranged from a high of 0.071 in 2006 to a low of 0.052 in 2011. This trend is similar to most of the sites in the western part of the state with the last four years having lower ozone levels. See Figure 7-18 to view a graph of the yearly 4th highest 8-hour average. The linear trends line shows a declining concentration level due to the last four years of testing.

Concentrations of ozone at this site were one of the highest concentrations in the state. Levels have decreased significantly in the last three years with concentrations now at the lowest in the state. This parameter will continue to be a priority at this location because of past concentration levels and the testing is meeting the needs to continue the sampling effort.

Figure 7-18 – Ozone Yearly 4th Highest 8-hour Averages

7.4.5 Badlands Site – Nitrogen Dioxide Data

The first year of testing at the Badlands Site for nitrogen dioxide occurred in 2005. As expected, concentrations for nitrogen dioxide are very low and represent background levels. Many hourly concentrations are at the detection limit of the analyzer at 1.0 ppb. The calculated annual average levels for all seven years are close to the detection level for nitrogen dioxide.

See Figure 7-19 to view a graph of the annual average concentrations. The linear trends line shows a stable concentration level. This parameter will continue to be a priority at this location and the testing is meeting the needs to continue the sampling effort.

Figure 7-19 – Badlands Site – Nitrogen Dioxide Annual Averages

7.5 Wind Cave Site

The Wind Cave National Park is one of two Class I areas in South Dakota designated for visibility protection under the Clean Air Act. The Wind Cave area is a large national park located in the southern Black Hills of South Dakota. The Wind Cave Site was established in 2005, with manual monitors for PM_{2.5} and continuous monitors for PM_{2.5}, PM₁₀, sulfur dioxide, nitrogen dioxide, and ozone. At the end of 2010, the manual PM_{2.5} monitors were removed from the site leaving only the continuous PM_{2.5} monitor for this parameter.

The monitoring equipment is located in a sampling shelter next to the IMPROVE site operated by the National Park Service. The site is located a short distance west of the visitor center. Figure 7-20 shows a current picture of the Wind Cave Site.

Figure 7-20 – Wind Cave Site

The IMPROVE data will be used to determine what type of sources are impacting the visibility of the national parks in South Dakota. The purpose of having a SLAMS site next to the IMPROVE site is to determine how the data compares between the two different sampling methods, to determine air pollution background levels, and to see if pollution trends show long range transport of air pollution from outside of the state. Table 7-6 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

7.5.1 Wind Cave Site – PM₁₀ Data

The PM₁₀ concentrations at this site are one of the lowest in the state and are similar in concentrations as the Badlands Site. The Wind Cave Site is the most remote site in the state and a site that has no influence from industry and agriculture activities near the location. Figure 7-21 contains a graph showing the annual average PM₁₀ concentrations.

The 2011, PM₁₀ concentrations remained about the same as in 2010. The trend line indicates a steady concentration levels over the seven years of testing. The concentrations ranged from 7 to 10 ug/m³ and are very low representing background levels. This parameter is meeting the goals of background, visibility protection, long range transport, and will be continued.

Figure 7-21 - Wind Cave Site PM10 Annual Averages

7.5.2 Wind Cave Site – PM 2.5 Data

The PM_{2.5} concentrations are similar to the levels recorded at the Badlands Site and are some of the lowest in the state. Figure 7-22 contains a graph showing the annual average PM_{2.5} concentration levels.

The linear trend line indicates a decrease in concentration level during the last four years of testing. The PM_{2.5} annual average concentration range from 6.5 ug/m³ in 2009 to 3.7 ug/m³ in 2011. This parameter is meeting the goals of background, visibility protection, and long range transport and will be continued.

Figure 7-22 Wind Cave Site PM2.5 Annual Averages

7.5.3 Wind Cave Site – Sulfur Dioxide Data

The yearly 1-hour 99th percentile for sulfur dioxide was kept in the annual plan to show trends and for comparison to other site data. The yearly 1-hour sulfur dioxide average for Wind Cave is very low. The graph in Figure 7-23 shows the concentration levels for the last three years. The linear trends line shows a steady sulfur dioxide concentration level. This parameter has met the goals of background, visibility protection, and long range transport. Because the concentrations of sulfur dioxide at the Badlands and Wind Cave sites are very close, the sulfur dioxide analyzer at Wind Cave was moved to the RC Credit Union Site in Rapid City at the start of 2011 because Rapid City has a higher potential for sulfur dioxide concentrations.

Figure 7-23 - Wind Cave Site Sulfur Dioxide 1-hour Average Yearly 99th Percentile

7.5.4 Wind Cave Site – Nitrogen Dioxide Data

The annual nitrogen dioxide averages are very low and are at the detection level for the analyzer similar to sulfur dioxide levels. The graph in Figure 7-24 shows the annual average concentration levels for the Wind Cave Site. The linear trend line shows a steady concentration level but with recorded levels at the detection level for the method trends are difficult to determine. This parameter has met the goals of background, visibility protection, and long range transport. This analyzer was also moved to the RC Credit Union Site in Rapid City at the beginning of 2011 because the nitrogen dioxide concentrations at the Badlands and Wind Cave sites are very close and the potential for nitrogen dioxide concentration is higher at the new location.

Figure 7-24 – Wind Cave NO2 Annual Averages

7.5.5 Wind Cave Site – Ozone Data

Figure 7-25 contains a graph of the ozone 8-hour concentrations for the Wind Cave Site since 2005. The Wind Cave Site had the highest reported yearly 4th highest 8-hour ozone level in the state at 0.073 parts per million recorded in 2006. Ozone levels began to fall in 2007 and now the site is the fourth highest site in the state.

Figure 7-25 – Wind Cave Ozone Yearly 4th Highest 8-hour Averages

The yearly 4th highest 8-hour average range from a high of 0.073 in 2006 to a low of 0.059 in 2008 and 2010. This trend is similar to the Badlands Site with the last four years having significantly lower ozone levels. The linear trends line shows a declining concentration level due to the last four years of testing. Testing for ozone is meeting the needs of the monitoring network by detecting transport pollution levels for this area of the state. Therefore, this parameter will be continued.

7.5 Sioux Falls Area

In 2011, two sampling sites were operated in the Sioux Falls area: 1) KELO and 2) SD School sites. The criteria pollutant parameters tested at these sites include PM₁₀, PM_{2.5}, ozone, sulfur dioxide, and nitrogen dioxide. In addition, special purpose parameters are sampled including continuous PM_{2.5}, PM_{10-2.5}, speciation PM_{2.5} and air toxics. Air monitoring data shows the Sioux Falls area is attaining all of the NAAQS set by EPA.

The city continues to grow and now includes residential areas in two counties: 1) Minnehaha and 2) Lincoln. Sioux Falls is the largest city in the state with a 2010 Census population of 169,468 for Minnehaha County and 44,828 in Lincoln County. The industrial base is mainly service oriented businesses with some heavy industry.

7.5.1 KELO Site

The KELO Site was established in 1991, as a replacement for the City Hall Site. Figure 7-26 shows a current picture of the monitoring site. The site is located in the downtown, central part of the city and at 21 years of operation is the oldest site still operating in Sioux Falls. The

Figure 7-26 – KELO Site

KELO Site is a SLAMS site for both PM₁₀ and PM_{2.5}. The sampling frequency for PM_{2.5} monitoring is every third day and the PM₁₀ monitor was changed to every sixth day at the beginning of 2009.

At the end of 2010, the PM₁₀ parameter was removed from this site because concentrations are low and have a very small chance of exceeding the national standard. Sampling objectives for these monitoring parameters are population and high concentration. The sampling scale is neighborhood for both PM₁₀ and PM_{2.5}.

In 2002, a PM_{2.5} speciation monitor was added to the site to determine the chemical makeup of the PM_{2.5} pollution. The sampler was located at this site because the PM_{2.5} concentrations are some of the highest in the state and because the city of Sioux Falls is the largest population center in the state. The PM_{2.5} speciation monitor was moved from this site to the SD School, NCore Site for South Dakota, at the beginning of 2009, as required by EPA rule.

During an oversight review completed by EPA in 2001, it was noted that a tree planted to the west of the sampling site had grown and would require that the sampling platform be moved about 10 feet east. The monitors were moved so the tree would not be an obstruction of the 360-degree arch around the monitor. In 2011, the distance between the monitors and the tree is sufficient so the tree is not an obstruction to the site. The height of the tree will be assessed each year to be sure the distance of the monitors from the tree meets the location requirements in 40 CFR Part 58. Table 7-7 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Table 7-7 - KELO Site Specifics

Parameter	Information

Analysis Methods	Gravimetric
Data Use	SLAMS (Comparison to the NAAQS)

7.5.1.1 KELO Site – PM_{2.5} Data

Sampling for PM_{2.5} concentrations began in 2001. Annual averages for the KELO Site have a range from a high of 10.7 ug/m³ in 2005 to a low of 8.7 ug/m³ in 2011. Figure 7-27 contains a graph of the annual averages for the KELO Site.

Figure 7-27 – KELO Site PM_{2.5} Annual Averages

Annual averages show some variation from year to year, but the trend line shows a slight decrease in concentration. In 2011, the annual average concentration decreased slightly to the lowest level.

The KELO Site is one the highest PM_{2.5} sites in the state for 24-hour hour and annual concentrations. Some years it has the highest 24-hour or annual level. In 2011, PM_{2.5} concentrations were the third highest site but all sites located along the eastern edge of the state were very close in levels. This parameter is meeting the goals of population and high concentration testing. This site continues to be an important site because of the historical concentration levels and testing will be continued.

7.5.2 SD School Site

The SD School Site replaced the SF Hilltop Site on January 1, 2008. The site is the National Core site for the state. Operating sampling parameters at the SD School Site include PM₁₀, PM_{2.5}, ozone, sulfur dioxide, nitrogen dioxide, carbon monoxide, PM_{10-2.5}, meteorology, PM_{2.5} speciation and air toxics in 2011. The setup of sampling equipment for PM_{10-2.5} includes results for PM₁₀ and PM_{2.5} without adding any additional monitors to the site. This is a very busy monitoring site collecting 140,465 data points per year all loaded to the EPA national database. Figure 7-28 shows a current picture of the SD School Site.

Figure 7-28 – SD School Site

The SD School Site is located on the east central part of the city. The site is about 1.2 miles southeast of the main industrial area in Sioux Falls. The area around the site is mainly residential. Interstate 229 which is a major commuting road runs north and south about three city blocks east of the monitoring site. Table 7-8 contains details on the monitoring site specific to the requirements in 40 CFR Part 58. In addition to the parameters listed in Table 7-8, an air toxic monitor samples every sixth day and PM_{2.5} speciation monitor is operated at an every 3rd day sampling schedule.

7.5.2.1 SD School Site – PM₁₀ Data

Figure 7-29 shows a graph of the annual averages since 2008. The annual averages at the SD School Site range from a high of 19 ug/m³ in 2010 to a low of 16 ug/m³ in 2009. In 2011, PM₁₀ concentrations were slightly lower than the previous year. The trend line indicates a slightly higher concentration level. This parameter is meeting the goals of high concentration and population and will be continued.

Figure 7-29 – SD School Site PM₁₀ Annual Averages

7.5.2.2 SD School Site – PM_{2.5} Data

PM_{2.5} data has been collected at this site since 2008. Annual averages for the SD School Site range from a low of 8.9 ug/m³ in 2011 to a high of 9.7 ug/m³ in 2010. The 2011 sampling year recorded a slightly lower concentration as was recorded in 2010. Figure 7-30 contains a graph of the annual averages.

Concentrations of PM_{2.5} are some of the highest in the state at this site. In 2011, the SD School Site had concentrations of PM_{2.5} that ranked as the second highest in the state. This parameter will remain a priority because concentrations are 61% of the annual standard. Testing for this parameter is meeting the goals of high concentration and population and will be continued.

Figure 7-30 – SD School Site PM2.5 Annual Averages

7.5.2.3 SD School Site – Ozone Data

Figure 7-31 contains a graph of each year's 4th highest ozone concentration level. The ozone analyzer runs on a continuous sampling schedule providing hourly concentrations to the data logger. The official yearly ozone season for South Dakota runs from June 1 to September 30.

Figure 7-31 – SD School Site Ozone Yearly 4th Highest 8-Hour Averages

Past sampling experience shows that some of the high ozone readings can occur outside of the official ozone season. The department operates the monitor year around instead of just during the ozone season.

Sampling began for ozone at this site in 2008. The highest annual 4th highest 8-hour ozone concentration was recorded in 2011 at 0.065 ppm. The lowest annual 4th highest 8-hour ozone concentration was recorded at 0.061 ppm in 2008. The trend line shows a slightly increasing level of ozone over the four years of testing. This parameter is meeting the goals of high concentration and population testing and will be continued.

7.5.2.4 SD School Site – Sulfur Dioxide Data

Testing for sulfur dioxide started in 2008 at this site. A continuous analyzer is operated providing hourly concentration levels. The levels of sulfur dioxide have dropped in concentration since the first year of testing. The type of analyzer was changed to a trace level sulfur dioxide analyzer in 2011. The detection level of this analyzer is 0.1 ppb.

In 2011, concentrations of sulfur dioxide continued to decrease. The trend line shows a sharp drop in concentrations of sulfur dioxide over the four years of testing. This parameter is meeting

the goals of high concentration and population and will be continued. Figure 7-32 contains a graph of the sulfur dioxide yearly 1-hour 99th percentile for each sampling year.

Figure 7-32 – SD School Site Sulfur Dioxide Yearly 1-hour 99th Percentile

7.5.3 SD School Site – Nitrogen Dioxide Data

The SD School Site began testing for nitrogen dioxide in 2008. The nitrogen dioxide analyzer provides hourly concentration levels. The SD School Site records the highest nitrogen dioxide concentrations in the state. There is only 1 ppb difference in annual concentration levels from highest annual average of 6.6 in 2008 and the lowest of 5.6 in 2009. Figure 7-33 shows the annual average for each of the years that data was collected. This parameter is meeting the goals of high concentration and population and will be continued.

Figure 7-33 – SD School Site Nitrogen Dioxide Annual Averages

7.6 Aberdeen Area

In 2011, one sampling site was operated in the city of Aberdeen at the Fire Station #1 Site. The Fire Station #1 Site was established in 2000 as part of the implementation of the PM_{2.5} air monitoring network. The parameters tested at the site include PM₁₀ and PM_{2.5}. The monitoring site is located in the center of the city on top of the fire station roof just east of the main downtown business area. The area around the site has service type businesses, county and city offices, and residential area to the east. See Figure 7-34 for a picture of the monitoring site.

Figure 7-34 – Aberdeen’s Fire Station #1 Site

In 2009, Fire Station #1 was renovated and a small addition was added to the south side of the building. The addition required no changes at the site so the location requirements in 40 CFR Part 58 are still met. Table 7-9 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Table 7-9 – Fire Station #1 Site Specifics

Parameter	Information

Data Use	SLAMS (Comparison to the NAAQS)

7.6.1 Fire Station #1 Site – PM₁₀ Data

In 2009 the sampling schedule for PM₁₀ changed from every third day to every 6th day because concentrations at the site continue to be low and the chance of recording a concentration over the current standard are very low. Figure 7-35 contains a graph of the annual averages since the site was setup in 2000.

Figure 7-35 – Fire Station #1 Site PM10 Annual Averages

The annual average concentrations change from year to year but with the addition of the annual average for 2011 the trends line indicates slight decline in levels over the twelve years of testing. The annual averages range from a low of 16 ug/m^3 in 2011 to a high concentration level of 24 ug/m^3 recorded in 2003 and 2008. The testing for this parameter is meeting the goals of high concentration and population and will be continued.

7.6.2 Fire Station #1 Site – PM_{2.5} Data

Sampling began for PM_{2.5} at this site in 2001. The PM_{2.5} monitors run on an every third day sampling schedule. Annual averages for the Fire Station #1 Site in Aberdeen have range from 7.7 ug/m^3 in 2008 and 2011 to 9.0 ug/m^3 in 2005. The 2011 annual average concentration was slightly lower then was recorded in 2010 by 1 ug/m^3 .

The trend line shows that annual average is declining slightly in concentration level over the last eleven years. The testing for this parameter is meeting the goals of high concentration and population and will be continued. Figure 7-36 contains a graph of the annual average concentrations.

Figure 7-36 – Fire Station #1 Site PM_{2.5} Annual Averages

7.7 Brookings Area

In 2011 two air monitoring sites were operated in the Brookings County. The oldest site is located at the City Hall building in the center of the city of Brookings. Testing at this site includes PM₁₀ and PM_{2.5} parameters. The Research Farm Site was setup in 2008 and is located at the Soil Conservation Farm northwest of the city of Brookings. Testing at this site includes ozone and meteorological data.

7.7.1 City Hall Site

The City Hall Site was established in 1989 and sampled for levels of PM₁₀. The site is the result of a cooperative effort between the department and the city of Brookings. The area to the west of the site is residential and the areas north, east, and south have service oriented businesses and light industry. Brookings is a growing community with a population of 22,056 and has a growing industrial base. In 1999, PM_{2.5} monitors were added to the site. The sampling frequency in 2011 for PM₁₀ was every sixth day and PM_{2.5} is every third day. Beginning in 2012 a continuous PM₁₀ monitor replaced the manual monitor at the site. Figure 7-37 shows a current picture of the monitoring site. Table 7-11 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Figure 7-37 – City Hall Site

7.7.1.1 City Hall Site – PM₁₀ Data

PM₁₀ sampling began at this site in 1989. The annual averages range from a high of 38 ug/m³ in 1990 to a low of 17 ug/m³ in 1993. The trend line shows concentration levels declining over the 22 years the site has been operating. In 2011, PM₁₀ concentrations were down slightly from the previous year. Testing for this parameter is meeting the goals of high concentration and population and will be continued. In Figure 7-38, there is a graph of the yearly annual averages since the site was setup in 1989.

Figure 7-38 – City Hall Site PM10 Annual Averages

7.7.1.2 City Hall Site – PM_{2.5} Data

The PM_{2.5} monitors run on an every third day schedule since the site was setup in 1999. Annual averages for the City Hall Site range from a high of 9.7 ug/m³ in 2003 and 2005 to a low of 8.0 ug/m³ in 2008. The trends for the eleven years of testing show a slight decrease in PM_{2.5} levels overall. In 2011, PM_{2.5} annual average concentration was slightly lower than recorded in 2010. Testing for this parameter is meeting the goals of high concentration and population and will be continued. Figure 7-39 contains a graph of the annual average concentrations.

Figure 7-39 – City Hall Site PM2.5 Annual Averages

7.7.2 Research Farm Site

The Research Farm Site was set up in cooperation with the 3M Company in Brookings and Valero Renewable Fuels Company near the city of Aurora which provided the equipment for the site. The sampling is a requirement of the Prevention of Significant Deterioration permits for both facilities. The department is operating the site and provided data to the facilities. The 3M Company has completed their air monitoring report using the data for 2008. Valero Renewable Fuels Company decided not to complete the facility upgrade under its Prevention of Significant Deterioration permit and no longer needs data from the Research Farm Site. Ozone data collected between 2008 and 2010 was added as a SLAMS site to the National Database in 2010.

The site location is outside of the nitrogen dioxide one microgram area modeled for the facilities in the Brookings area. The site collects data for ozone and meteorological parameters. The goals of the monitoring site were the evaluation of impacts to the ozone concentrations from modification at the 3M Company and Valero Renewable Fuels Company and to date the goals have been met. New goals have been added to collect ozone data downwind of a small city and for comparison to the NAAQS. The completion of the 2011 sampling year provides the four years of testing and a better idea of trends for the site ozone data. Figure 7-40 shows a current picture of the monitoring site. Table 7-11 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Data Use	PSD (Comparison to the NAAQS),

7.7.2.1 Research Farm Site – Ozone Data

The 2011 sampling year is the fourth ozone season of testing. The goal was to collect at least three years of data before any changes are made to the site. In 2011, the Research Farm Site had a yearly fourth highest 8-hour average that was under the standard of 0.075 ppm. The current

ozone data indicates an increasing level. The ozone sampling sites along the eastern edge of state have all had a slight increase in ozone levels the last four years. This is in contrast to the west river sites that have decreasing ozone concentrations and they went from the highest concentration sites to now the lowest after the last four years.

The testing for this parameter is meeting the goals of a SLAMS location and will be continued because as one the three sites recording the highest concentrations in the state it is meeting the goal of high concentration and population. The graph in Figure 7-41 shows the yearly 4th highest ozone concentration level for the last four years.

Figure 7-41 – Research Farm Site Ozone Yearly 4th Highest 8-Hour Averages

7.8 Watertown Area

In 2011, one sampling site was operated in the city of Watertown and is identified as the Watertown Site. Watertown is the fourth largest city in South Dakota with a population of 21,482. The city has an increasing growth rate and industrial base. The industrial base is a mixture of service-oriented business and light industry. One other air monitoring site was operated in Watertown starting in 1974 and closed 1987. No other air monitoring data has been operated in the city. Figure 7-42 shows a picture of the monitoring site.

The Watertown Site was established in 2003 as part of the implementation of the PM_{2.5} network. The parameters tested at the site include PM₁₀ on a sampling frequency of every day and PM_{2.5} at a sampling frequency of every third day. The monitoring site is located in the western third of the city just east of an industrial park area. The site is located on the roof of a monitoring shelter. The area around the site has service type businesses and light industry to the west and south. Residential areas are located to the north and east of the site. There have been no significant

changes noted in buildings or trees around the site during this review. Table 7-12 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

7.8.1 Watertown Site PM₁₀ Data

The PM₁₀ monitor operated on an every third sampling schedule until 2006 when a continuous PM₁₀ monitor replaced the manual monitors and an everyday sampling schedule began. The highest recorded annual average for PM₁₀ concentrations was 28 ug/m³ recorded in 2003. The lowest annual average concentration of 20 ug/m³ was recorded on the manual monitor in 2005 and 2011. In 2011, concentrations were down slightly from the previous year at 20 ug/m³. The annual average indicates concentration levels are slightly decreasing during the nine years of testing. Testing for this parameter is meeting the goals of high concentration and population and will be continued. Figure 7-43 contains a graph of the annual averages.

Figure 7-43 – Watertown Site PM₁₀ Annual Averages

7.8.2 Watertown Site PM_{2.5} Data

The PM_{2.5} monitors run on an every third day schedule since the PM_{2.5} monitors were setup in 2003. Annual averages for the Watertown Site range from a high of 10.7 ug/m³ in 2005 to a low of 8.1 ug/m³ in 2011. The 2011 annual average was down slightly from the previous year. The annual average shows a decrease in PM_{2.5} concentration levels over the nine years of testing. Testing for this parameter is meeting the goals of high concentration and population and will be continued. Figure 7-44 contains a graph showing the annual average concentration for each year of operation.

Figure 7-44 – Watertown Site PM2.5 Annual Averages

7.9 Union County Area

At the beginning of 2009, three new monitoring sites were set up in Union County. No ambient air quality testing has ever been completed in this county. All three sites are located north of Elk Point. The new sites will determine air pollution levels near the location of the proposed Hyperion Energy Center prior to construction, during construction, and post construction. In addition the data will be compared to the NAAQS. The Hyperion Energy Center when constructed would be home to an oil refinery and electrical power plant. Because the sites are collecting preconstruction or background data the parameters will be compared between UC #1 and UC #2 sites.

7.9.1 UC #1 Site

UC #1 Site is located about 3 miles south of the proposed Hyperion Energy Center. Sampling began on or near January 1, 2009 for all but carbon monoxide. Problems with the new carbon monoxide analyzer were encountered and needed to be worked out. By the beginning of 2010, the carbon monoxide data was meeting the quality assurance measures. The goals of the site are background and comparison to the NAAQS. Figure 7-45 provides a picture of the monitoring site looking to the southeast.

Figure 7-45 – UC #1 Site

7.9.3 UC #1 and UC #2 Sites – PM₁₀ Data

The average concentrations of PM₁₀ in Union County represent concentration levels similar to other sites in eastern South Dakota. The annual average concentrations in eastern part of the state range from 15 to 22 ug/m³. The Union County sites annual averages ranked in the middle to the lower end of this range. See the annual averages for the two sites in Union County in Figure 7-47.

PM₁₀ point source emissions have localized impacts due to the size and weight of the particles. Therefore, low annual averages close to the same concentration level at both sites would be expected in a rural area with only fugitive dust sources. Because of differences in localized fugitive dust sources such as tilling of agricultural fields, gravel roads, and associated wind speed and direction during the activities can have a larger effect on differences in 24-hour concentration levels between the two sites. Trends indicate concentrations are down slightly for UC #1 and UC #2 has a steady PM₁₀ concentration level.

Figure 7-47 – Union County Annual PM₁₀ Concentrations

7.9.4 UC #1 and UC #2 Sites – PM_{2.5} Data

The annual average concentrations for PM_{2.5} at the two sites would be expected to be close to the same level. In this case the annual averages were compared between both continuous monitors. See Figure 7-48 to view a graph of the annual averages.

Figure 7-48 – Union County Annual PM_{2.5} Concentrations

A difference of 1 ug/m³ was shown between the two sites with UC #2 having the highest concentration in 2009. In 2010, both sites had the same annual average concentration of PM_{2.5}.

In 2011, concentrations of PM_{2.5} were at a difference of 1.2 ug/m³ with UC #1 having the highest level.

When comparing the activities around the two sites the differences include a highway running just north of UC #2 and a small group of homes and business near this site. UC #1 has only one home near the site. Therefore, there may be some concentration difference between the two sites. It appears the differences did not affect the annual average levels as the 3-year average of annual means shows almost no difference between the two sites with UC #1 only 0.1 ug/m³ higher than UC #2.

At UC #2 both a manual method monitor and a continuous method monitor are operated. One notable item is the difference in the annual averages in 2009, between the manual and continuous method at UC #2 was only 0.3 ug/m³. The difference in annual averages between both methods in 2010 and 2011 was only 0.1 ug/m³ per year. So the difference between the two methods may be more related to the sampling frequency than method differences.

Annual average concentrations in the eastern part of the state range from 9.1 to 7.4 ug/m³. It appears that both UC #1 and UC #2 represent the current background PM_{2.5} concentrations because the annual averages for both sites have only a small difference in level.

7.9.5 UC #1 and UC #2 Sites – Sulfur Dioxide Data

Concentrations of sulfur dioxide follow the same trend as other sites in the state with many hour average concentrations low near the detection level (0.1 ppb) for the analyzer method being used to collect the data. Trace level sulfur dioxide analyzers are operated at both sites beginning in 2009. See Figure 7-49 for a graph showing the 1-hour 99th percentile for both sites.

Figure 7-49 – Union County Sulfur Dioxide Concentrations

Differences in concentration levels are noted between the two sites when comparing the 1-hour averages but the 3-year average of the 99th percentile for both sites shows the level at UC #1 only 1.5 ppb higher than UC #2.

7.9.6 UC #1 and UC #2 Sites – Nitrogen Dioxide Data

Concentrations of nitrogen dioxide follow the same trends as other rural sites in the state like the Badlands and Wind Cave sites. Annual average concentrations are very low near the detection level for the analyzer method being used to collect the data. Just as the sulfur dioxide parameter, the nitrogen dioxide parameter differences are noted when comparing a 1-hour average but the annual averages are very close in concentration. Figure 7-50 shows a graph of the annual average concentration for both sites.

Figure 7-50 – Union County Nitrogen Dioxide Concentrations

7.9.7 UC #1 Site – Carbon Monoxide Data

The testing for carbon monoxide is done only at UC #1 Site. Testing began in 2010 and at the end of 2011 two years of testing has been completed. Carbon monoxide concentrations are very low in Union County. The concentrations of carbon monoxide represent background for a rural area in southeastern part of the state. Figure 7-51 shows the results of testing for carbon monoxide at UC #1 Site.

Figure 7-51 – UC #1 Site Carbon Monoxide Concentrations

7.9.8 UC #3 Site

UC #3 Site is located about 3 ½ miles north and 2 miles west of the proposed Hyperion Energy Center. Figure 7-52 contains a picture of the monitoring site looking northeast.

Figure 7-52 – UC #3 Site

Table 7-15 contains details on the monitoring site specific to the requirements in 40 CFR Part 58.

Site Name	UC #3
AQS ID Number	46-127-0003
Street Address	31102 47 th Ave.
Geographic Coordinates	Lat. + 42.880212 Long. – 96.785339
MSA	Sioux City, IA-NE-SD
Ozone	(Continuous)
Sampler Type	Federal Equivalent Method EQOA-0880-047
Operating Schedule	Every Day
Scale Representation	Regional
Monitoring Objective	Background, Transport
Sampling Method	Thermo 49i
Analysis Method	Ultraviolet
Data Use	PSD and (Comparison to the NAAQS),

The ozone 8-hour average for the UC #3 Site recorded a concentration that was similar to levels recorded at the other two sites in the eastern part of the state in 2011. The trend line shows a slight increase in concentrations over the last three years. This is similar to the other two sites in the eastern part of the state. See Figure 7-53 for a graph of the ozone concentrations at the UC #3 Site.

Figure 7-53 – UC #3 Site Ozone Concentrations

8.0 SPECIAL AIR QUALITY MONITORING

8.1 Urban Air Toxics Monitoring Program

South Dakota has two stations that collect samples as part of the Urban Air Toxics Monitoring Program (UATMP). These stations collect 24-hour air samples on a 6-day schedule.

One site is in Sioux Falls (SSSD), located in southeastern South Dakota. Sioux Falls is the largest city in the state. The site is located near School for the Deaf and residential areas. The main industrial area of the city is about 1.2 miles northwest of the site. The site was selected because it represents population exposure to chemical and particulate emissions from the industrial parts of the city. The predominant wind direction is northwest for most of the year with southeast winds during the summer months. The monitor was relocated in 2008 about 1.2 miles northwest of the previous site (SFSD). The previous monitor was setup in March of 2000, sampling for hydrocarbons, halogenated hydrocarbons, and polar compounds. In 2002, carbonyls sampling was added.

The other site is in Union County (UCSD), also located in southeastern South Dakota. The UC#1 Site is located about 3 miles south of the proposed Hyperion Energy Center. The department added three new air monitoring sites to the network in 2009. A proposed oil refinery and power plant project called the Hyperion Energy Center is planned in Union County in an area north of Elk Point. This project would collect air monitoring data for the first time in Union County. The monitoring project objectives are to gather data to determine current pollution levels before construction of the project begins, collect data during plant construction, and determine levels during the operation of the facility. Sampling began on or near January 1, 2009.

Table 8-1 shows a comparison of the two cities for the five pollutants we are concentrating on. It shows which site had the higher concentration in 2011, what the overall trend has been in Sioux Falls and Union County, and what the sources are for these pollutants. Sioux Falls had the higher concentrations in 2011 for 1,3-Butadiene, Formaldehyde, Acrolein and Benzene and Union County had the higher concentrations in 2011 for Acetaldehyde. The trend for these pollutants has been decreasing except for Acrolein in Sioux Falls.

Table 8-1 – Air Toxic Sampling Results for 2011

Air Toxic Pollutant	Site	Site with higher 2011 ppbc	Trend	Possible Sources
1,3-Butadiene	UC		Decrease	Motor vehicle exhaust, manufacturing and processing facilities, forest fires or other combustion, and cigarette smoke
	SF	X	Decrease	
Formaldehyde	UC		Decrease	Power plants, manufacturing facilities, incinerators, and automobile exhaust emissions
	SF	X	Decrease	

Air Toxic Pollutant	Site	Site with higher 2011 ppbc	Trend	Possible Sources
Acetaldehyde	UC	X	Decrease	An intermediate product of higher plant respiration and is formed as a product of incomplete wood combustion in fireplaces and wood stoves, coffee roasting, burning of tobacco, vehicle exhaust fumes, and coal refining and waste processing.
	SF		Decrease	
Acrolein	UC		Decrease	Formed from the breakdown of certain pollutants found in outdoor air, from burning tobacco, or from burning gasoline.
	SF	X	Increase	
Benzene	UC		Decrease	Found in emissions from burning coal and oil, motor vehicle exhaust, and evaporation from gasoline service stations and in industrial solvents
	SF	X	Decrease	

The department also opted to have total non-methane organic compounds (NMOC) sampled. NMOC compounds are of particular interest because of their role in ozone formation. The average total NMOC values are shown in Figure 8-1. The 2008 through 2011 values in Sioux Falls are from the SSSD site and the previous values were from the SFSD site.

Figure 8-1 – Average Total NMOC

8.2 PM_{2.5} Speciation Monitoring Program

The chemical speciation network will quantify mass concentrations and significant PM_{2.5} constituents which include trace elements, sulfate, nitrate, sodium, potassium, ammonium, and carbon. This series of analytes is very similar to those measured within the Interagency Monitoring of Protected Visual Environments (IMPROVE) program.

Physical and chemical speciation data are anticipated to provide valuable information for:

1. Assessing trends in mass component concentrations and related emissions, including specific source categories;
2. Characterizing annual and seasonal spatial variation of aerosols;
3. Determining the effectiveness of implementation control strategies;
4. Helping to implement the PM_{2.5} standard by using speciation data as input to air quality modeling analyses;
5. Aiding the interpretation of health studies by linking effects to PM_{2.5} constituents; and
6. Understanding the effects of atmospheric constituents on visibility impairment and regional haze.

South Dakota has one site that collects samples as part of the Speciation Network. This site collects 24-hour air samples on an every 6-day schedule. In 2011, the sampling frequency was increase to every 3-day schedule as was required for an NCore site. The site is in Sioux Falls, located in southeastern South Dakota. Sioux Falls is the largest city in the state.

The speciation monitor was moved from the KELO site to the SD School Site at the beginning of 2009. The SD School Site is located on the east central part of the city. The site is about 1.5 miles southeast of the main industrial area in Sioux Falls. The area around the site is mainly residential. Interstate 229 which is a major commuting road runs north and south about three city blocks east of the monitoring site. The predominant wind direction is northwest for most of the year with southeast winds during the summer months. Carbon samples were taken by the Met One SASS monitor. In September 2009, the Improve URG 3000N sampler was set up to do the carbon sampling. Figure 8-2 shows a comparison of the PM_{2.5} concentrations between the PM_{2.5} speciation monitor, the manual PM_{2.5} monitor, and the continuous PM_{2.5} monitor located at this site.

The continuous monitor shows a decrease in concentrations over the three years of testing. The manual monitors show a slightly decreasing concentration. The speciation monitor shows an increasing concentration level. This is an unusual trend between the monitor types. It appears that sampling frequency may be the major issue on the difference in trends. The first two years of testing the speciation monitor ran on an every 6th day schedule. In 2011, the schedule was changed to every third day. This reduced some of the difference in annual average concentration and brings the speciation monitor annual average comparable to the continuous monitor annual average.

Figure 8-2 – Average PM_{2.5} Concentration

Figure 8-3 shows the average total organic carbon and elemental carbon concentrations for the URG. Concentrations of carbon are low. The organic carbon concentrations on the average were slightly higher in 2011 than in 2010. The average contribution of elemental carbon to the overall concentration increased slightly between 2010 and 2011. The overall trend for total carbon shows a slight increase of the three years of testing.

Figure 8-3 – Average Carbon Concentrations

Figure 8-4 shows the average nitrate and sulfate concentrations analyzed from the PM_{2.5} samples. The graph shows trends for the concentration of nitrates are at nearly a steady level over the seven year period. Sulfates in the PM_{2.5} samples declined an average of 0.5 ug/m³ during the testing period.

Figure 8-4 – Average Nitrate and Sulfate Concentrations

9.0 NETWORK MODIFICATIONS FOR 2011 and 2012

9.1 New Sites

The department will continue to evaluate the following areas for the need to modify the ambient air monitoring network:

1. With the change in deicing operations in Rapid City, the department will continue to evaluate the need for other air monitoring sites in the city if problems with dust are noted.
2. As monitoring rules and standard are finalized by EPA in 2011 there may be a need for modifications to the ozone testing site locations.
3. EPA has revised the sulfur dioxide standard and the rule requires population weighted emission averaged site in the Sioux City MSA which includes Union County in South Dakota. The department will be evaluating the rule change and the impact on the state's ambient air monitoring network.

9.2 Modifications

The department is planning the following site modifications:

1. Replacement of the RAAS PM_{2.5} manual method monitors with Partisol 2000 PM_{2.5} manual method monitors continues. The RAAS PM_{2.5} manual method monitors, purchase in 1997 to 2000, have been discontinued by the manufacturer and replacement parts are no longer available. Rapid City Library Site is the last site to operate the RAAS PM_{2.5} monitors and they will be replaced by the middle of 2012; and
2. The department will continue to evaluate locations where continuous PM monitors can replace manual monitors in the network.

9.3 Sites Closed

The department will evaluate the need to close UC #3 and move the ozone analyzer to UC #2 or UC #1. The shelter at UC #3 is in poor condition which has allowed water and mice into the building destroying the insulation and making the building a health threat.

10.0 REQUEST FOR WAIVER

There were no sampling frequency waivers requested for the 2011 sampling year and none are proposed for 2012.

11.0 CONCLUSIONS

The ambient air quality monitoring network has demonstrated or is in the process of demonstrating that South Dakota is attaining the federal NAAQS. The Air Quality Program is working to ensure that any changes in the air quality of the state are reviewed for possible health effects to the public. The ambient air quality monitoring network is continually reviewed to ensure that there is adequate coverage of populated areas in the state. As the state's population and industry changes, monitoring sites will be added or moved to new locations.

There is an ongoing effort to maintain staff training regarding the latest monitoring techniques and procedures to perform these studies. It is anticipated that the ambient air monitoring network will operate in much the same manner as it has in the past. This will include the identification of pollution problems, measurement and evaluation of the extent of the problem, and determination of action to be taken to protect the environment and the health of the people of South Dakota.
